## 1 EXECUTIVE SUMMARY

This document summarises the ERS-2 SAR instrument and product quality status as derived from data acquired up to and during repeat period cycle 143 from 22nd December 2008 to 26th January 2009. During this period several SAR acquisitions were made with very high satellite yaw angles.

The status of the instrument is provided in chapter 2 including details of any data disclaimers issued during the reporting period. Information on the internal calibration of both image and wave modes is presented in chapter 3. The radiometric stability of the ERS-2 SAR has been assessed via various approaches – transponders, the Amazon rainforest and ground stations, as described in chapter 4. Chapter 5 describes the important image quality parameter of noise equivalent radar cross-section. Details on the Doppler Centroid evolution are provided in chapter 6. Finally a list of auxiliary data files applicable to the ERS-2 SAR is provided in chapter 7.

A summary of the performance of the ERS-2 SAR can be found on the ESA Product Control Service web site at <http://earth.esa.int/pcs/ers/sar/articles/>.

Note that this ERS-2 SAR cyclic report is the first since cycle 106 (June/July 2005).

## 2 INSTRUMENT STATUS

During the reporting period some ERS-2 SAR imagery was acquired with very high Doppler centroid frequencies and hence very high yaw angles. Doppler centroid frequencies of up to 15000 Hz and yaw angles up to 11° have been found. This problem is caused by the Digital Earth Sensor (DES) being occasionally blinded by the Sun. Such blinding is autonomously detected on board and the spacecraft is left drifting until valid DES data are available again. This problem has been identified from previous years but not to the same extent as found during the reporting period.

### 2.1 *Instrument Unavailability*

There were no instrument unavailabilities during the reporting period.

### 2.2 *Data Disclaimer*

A data quality disclaimer is issued each time that ERS-2 SAR data of degraded quality is acquired between specific time intervals. New disclaimers were issued for data acquired during the reporting period:

**On 23-DEC-2008, 26-DEC-2008, 04-JAN-2009, 14-JAN-2009, 17-JAN-2009 & 20-JAN-2009**

#### **Warning:**

High Doppler centroid frequencies and large azimuth localisation accuracies.

#### **Problem Description:**

Due to a problem with the ERS-2 SAR satellite, some imagery was acquired with very high Doppler centroid frequencies and hence large yaw angles. Data acquired under large yaw angles may be de-focussed and have large azimuth localisation accuracies of up to 5km.

#### **Affected products:**

All ERS-2 SAR products, including level 0 products.

### 2.3 *ERS-2 Mission Operations*

Information about the operation of the ERS-2 mission can be found at:  
<http://earth.esa.int/ers/technicalstatusreport/>.

## 3 INTERNAL CALIBRATION

### 3.1 *Image Mode Internal Calibration*

The internal calibration of the ERS-2 SAR is assessed via calibration pulse, replica pulse and noise signal powers. The calibration pulse and noise signal are available at the start and end of each SAR imaging sequence while the replica pulses are available throughout an imaging sequence. The calibration pulse measures the majority of any gain drift from image sequence to image sequence while the replica pulse monitors any gain drift during the imaging sequence when the more representative calibration pulse is not available. In fact, the power of the calibration pulse is the best guide we have for the transmitted pulse power.

Figure 3.1 shows the calibration pulse power, replica pulse power and noise pulse power from the start of the ERS-2 mission. The calibration pulse power plot shows significant change of power during an image sequence, especially during recent years. ERS-2 SAR products generated within the ESA ground segment compensate for any variation in calibration pulse power during an imaging sequence (although there is an impact on the noise equivalent radar cross-section – see chapter 6). Note that the replica and noise pulse powers are only shown for the start of each imaging sequence.

Further details on the internal calibration on the ERS-2 SAR can be found in the paper on the ESA Product Control Service web site (<http://earth.esa.int/pcs/ers/sar/articles/>).

Figure 3.1(a). ERS-2 SAR Calibration Pulse Power

Figure 3.1(b). ERS-2 SAR Replica Pulse Power

Figure 3.1(c). ERS-2 SAR Noise Pulse Power

### 3.2 *Wave Mode Internal Calibration*

As with image mode, a calibration pulse power is available for wave mode. Figure 3.2 shows the daily averaged calibration pulse power since 1996.

Figure 3.2 ERS-2 Wave Mode Calibration Pulse Power

## 4 RADIOMETRIC STABILITY

The stability of the ERS-2 SAR has been measured using three ESA transponders (up to end 2001), the Amazon rainforest and ground receiving stations in Kiruna, Sweden and Neustrelitz, Germany.

Three ESA transponders were deployed across Flevoland, The Netherlands from the start of the ERS-2 mission in April 1995 until February 1997, April 2001 and November 2001 respectively. The measured radar cross-sections of the transponders were compared to their actual radar cross-section values. This relative transponder radar cross-section (after the power loss calibration correction has been applied) is shown in Figure 4.1. The measured mean radiometric accuracy, mean radiometric stability and peak to peak rcs for the ERS-2 SAR using the ESA transponders are shown in Tables 4.1 and 4.2. These tables indicate an excellent radiometric stability for the ERS-2 SAR. In addition, the radiometric accuracy value is very good while the peak to peak radar cross-section value is acceptable.

Figure 4.1. ERS-2 SAR Relative Radar Cross-sections for the ESA transponders.

Transponder	Operation Dates	Mean Accuracy (dB)	Mean Stability (dB)	Peak-Peak RCS (dB)	No of Images
ERS Tran. #1	19-Jul-95 – 05-Feb-97	0.04	0.29	1.54	28
ERS Tran. #2	19-Jul-95 – 30-Nov-01	0.33	0.34	1.39	100
ERS Tran. #3	19-Jul-95 – 25-Apr-01	0.11	0.18	0.88	92

Table 4.1. ERS-2 SAR Radiometric Results from ESA Transponders

Radiometric stability	0.27dB
Radiometric accuracy	0.16dB
Peak to peak radar cross-section	1.27dB

Table 4.2. Mean ERS-2 SAR radiometric results from the ESA transponders

ERS-2 SAR images of the Amazon rainforest have also been used to derived radiometric stability. The dataset is based on two nearby scene sites (track 139 and frame 3735 at centre latitude 6° 20'S, longitude 67° 13'W and track 146 and frame 7059 at centre latitude 6° 30'S, longitude 67° 33'W). Figure 4.2 shows gamma ( $= \sigma_0 / \cos(i)$  where  $\sigma_0$  is radar cross-section and  $i$  is incidence angle) derived from each image after the masking of none rainforest areas. The mean gamma for the first site is -6.05dB while the stability is 0.13dB and for the second site the mean gamma is -5.99dB with a stability of 0.20dB. These stability values are comparable to the values derived using the ESA transponders.

Figure 4.2. ERS-2 SAR Amazon Rainforest Stability

Ground stations can also be used to assess the stability of the ERS-2 SAR. As the ground station receiving dishes are acquiring and receiving data in real-time they will be pointing towards to satellite and hence appear as a point target in the SAR imagery. For the two 15m receiving dishes at Kiruna, the point target response in processed imagery is so strong that it is saturated in the processed imagery. However, the azimuth ambiguities are not saturated and so have been used for

stability assessment. At Neustrelitz there are three nearby 7.3m diameter receiving dishes which have a point target response that are not saturated in processed imagery and so can be used directly for stability assessment.

Table 4.3 gives the mean radar cross-section, stability and peak to peak radar cross-section values of the Kiruna ambiguities. These results are slightly higher than the transponder results given in Table 4.1. Figure 4.3 shows the ERS-2 Kiruna ambiguity radar cross-section for the two antennae (KS1 and KS2). For KS1 a change in the rcs measurements occurs at the same time as the start of gyro-less attitude control operation in early 2001. The measurement indicated by the red symbol has been corrected by 4dB due to the replica pulse problem that occurred from imagery acquired between 4th September and 14th October 2004. Since last 2006 the ERS-2 SAR products have been processed with the PGS-ERS processor rather than the VMP. It has been found that the azimuth ambiguity ratio from PGS-ERS images is about 3dB higher than from VMP images. In Figure 4.3 and Table 4.3 the PGS-ERS measurements have been corrected by 3dB (the dark blue measurements). All the KS2 measurements have been made using the PGS-ERS processor and include the 3dB correction. Hence the difference in rcs between KS1 and KS2 can be attributed to the receiving dishes themselves.

Note that the mean KS1 ambiguity radar cross-section derived using ERS-1 and ERS-2 imagery has been found to be similar indicating a good relative radiometric calibration between the two sensors.

Ground Station	Acquisition Dates	RCS (dBm <sup>2</sup> )	Mean Stab. (dB)	P-P RCS (dB)	Num Results
KS 1	20-Jul-95 to 09-Oct-07	48.05	0.59	3.10	136
KS 2	18-Jan-07 to 12-Jan-09	43.05	0.53	2.17	20
NZ 1	13-Apr-96 to 03-Jan-09	58.94	0.51	3.07	126
NZ 2	15-Jan-98 to 28-Oct-08	59.34	0.52	2.96	88
NZ 3	09-Jan-03 to 01-Apr-08	63.59	0.33	1.78	48

Table 4.3. ERS-2 SAR radiometric results derived from the Kiruna (KS) and Neustrelitz (NZ) ground stations

Table 4.3 also gives the mean radar cross-section, stability and peak to peak radar cross-section values for the three Neustrelitz receiving dishes. Figure 4.4 shows the ERS-2 Neustrelitz ground station radar cross-sections. Although the three Neustrelitz ground stations are of the same diameter, the rcs of the newest antenna is significantly higher than the other two antennae. This is likely to be due to differences in the properties of each receiving dish. With the introduction of products from the PGS-ERS processor it was found that there was a jump in the measured rcs of the NZ3 receiving dish. This change was found to be due to the increase in the number of bits used in the detected product (from 15 to 16) which indicated that VMP measurements of this antennae were saturated (this was not the case of the NZ 1 and NZ 2 antennae). The radiometric stability and peak to peak RCS results are slightly higher than for the ESA transponder. Examination of Figure 4.4 shows there are a small number of radar cross-section measurements that are significantly

lower than the majority. Four of these occur when the ground station IRF is at extreme low and high incidence angles; it is suggested that the ground station itself is contributing to the larger than expected radar cross-section variations through mis-pointing and/or weather effects.

Figure 4.3. ERS-2 Kiruna ground station stability.

Figure 4.4. ERS-2 Neustrelitz ground station stability.

## 5 NOISE EQUIVALENT RADAR CROSS-SECTION

The upper limit to the noise equivalent  $\sigma^0$  ( $NE\sigma^0$ ) of an image can be estimated by measuring the radar cross-section of low intensity regions (usually ocean/inland water regions). Figure 5.1 shows low intensity region radar cross-section measurements from PRI/IMP images (after removing the range dependence in  $NE\sigma^0$  due to the elevation antenna pattern, range spreading loss and  $\sin(i)/\sin(23^\circ)$  to give a  $NE\sigma^0$  at the mid-swath position). The  $NE\sigma^0$  measurements after the gain changes at the end of February 2003 are coloured red.  $NE\sigma^0$  measurements extracted from imagery acquired between 4th September and 14th October 2004 have been reduced by 4dB to correct for the erroneous calibration attenuation gain setting during this period (coloured green). The brown data points are measurements made with PGS-ERS products. The trend line in Figure 5.1 is for (i) a 0.66dB per year decrease in transmitter pulse power between launch and the end of 2000, (ii) a decrease of 0.82dB per year until the end of February 2003, (iii) a 2dB drop at the end of February 2003 and then (iv) the resumption of the 0.66dB per year decrease.

Figure 5.1. ERS-2 PRI/IMP estimate of Noise Equivalent Radar Cross-Section (at the mid-swath position) as a function of acquisition date.

An offset of 26.3dB has also been used for the trend line; -26.3dB represents the  $NE\sigma^0$  at the start of the ERS-2 mission. Note that during mid-2000 and since mid-2001 there are  $NE\sigma^0$  values below the trend line - this is due to imagery being used with higher replica and calibration pulse powers than the general downward trend in these powers. As the  $NE\sigma^0$  is directly related to the

calibration and replica pulse powers, Figure 5.2 shows the  $NE\sigma^0$  as a function of replica pulse power (the replica pulse power at the start of the mission has been set to 52.1dB). The lower trend line is a linear relationship between  $NE\sigma^0$  and replica pulse power prior to the gain change at the end of February 2003 while the middle trend line is for this relationship after the gain change. Finally the upper trend line is for recent NESigma0 measurements from PGS-ERS products which are about 0.5dB higher than the post February 2003 VMP trend line. Figure 5.2 shows more clearly the reduction in  $NE\sigma^0$  since the start of the ERS-2 mission.

Figure 5.1. ERS-2 PRI/IMP estimate of Noise Equivalent Radar Cross-Section (at the mid-swath position) as a function of replica pulse power.

## 6 DOPPLER MONITORING

Figure 6.1 shows the Doppler centroid frequency and satellite yaw angle since the start the year 2000 when that attitude of the satellite was monitored by one gyroscope rather than 3 previously. Details of the evolution of the Doppler and yaw can be found in the ERS-2 SAR paper available on the ESA Product Control Service web site (<http://earth.esa.int/pcs/ers/sar/articles/>) – the recent high Doppler and yaw are explained in chapter 2.2 above.

Figure 3.1. ERS-2 SAR Doppler Centroid (top) and Yaw (bottom) Evolution since January 2000

ERS-2 Orbit Control Manoeuvres (OCM) can affect the platform attitude stability even hours after the burst with a direct impact on the Doppler centroid frequency evolution. An updated list of the OCM can be found at <http://nng.esoc.esa.de/ers/ERSman.html>.

## 7 AUXILIARY FILES

ERS-2 SAR auxiliary files contain information on calibration, the elevation antenna pattern and other instrument parameters. The files issued to date are:

ER2\_XCA\_AXNXXX20050321\_000000\_19950101\_000000\_20100101\_000000

ER2\_CON\_AXNXXX20050321\_000000\_19950101\_000000\_20100101\_000000

Note that the first date in the auxiliary files is the creation date, while the following dates indicate the start and stop of the file validity period. These files can be downloaded from <http://earth.esa.int/pcs/ers/sar/aux/>.
