
ERS-2 Wind Scatterometer Cyclic Report

From 13th December 2004 to 17th January 2005
Cycle 101

Prepared by: PCS Team
Inputs from: H. Hersbach (ECMWF)

Issue: 1.0
Reference: ERSE-SPPA-EOPG-TN-05-0002
Date of issue: 15th March 2005
Status: Approved
Document type: Technical Note
Approved by: P. Lecomte

Table of Content

1	Introduction and Summary	3
2	Calibration Performances.....	5
2.1	Gain Constant over transponder.....	5

4.3.2	UWI minus First-Guess history	36
4.3.3	Scatter plots.....	44
5	Yaw error angle estimation.....	50

1 Introduction and Summary

The document includes a summary of the daily quality control made within the PCS and various sections describing the results of the investigations and studies of “open-problems” related to the Scatterometer. In each section results are shown from the beginning of the mission in order to see the evolution and to outline possible “seasonal” effects. An explanation for the major events which have impacted the performance since launch is given, and comments about the recent events which occurred during the last cycle are included. This report covers the period from 13th December 2004 to 17th January 2005 to (cycle 101) and includes the results of the monitoring activity performed by ESRIN and ECMWF.

- This document is available on line: http://earth.esa.int/pcs/ers/scatt/reports/pcs_cyclic/

Mission events

- The ERS-2 satellite was piloted in ZGM throughout the cycle 101.
- During cycle 101 the ESACA processor worked nominally without faults.
- ERS-2 Data was not acquired on December 26th 2004 (00:26 a.m. – 06:51 p.m.) due to an IDHT anomaly
- On 16th December 2004 an AMI memory test has been successfully executed.
- The AMI instrument was unavailable from December 26th (10:17 p.m.) to December 28th 2004 (08:44 p.m.) due to an onboard anomaly.
- On 12th January 2005, due to a meteorological forecast dissemination problem, Scatterometer fast delivered data has been processed without background winds.
- For the entire period in cycle 101, ERS-2 Scatterometer data was used in the 4D-Var data assimilation system at ECMWF.
- News on ERS mission is available on line: http://earth.esa.int/ers/new_ers_news.html

Yaw performance

- The result of the yaw monitoring for cycle 101 is a yaw error angle within the expected nominal range (+/- 2 degrees) with an average level around 0 deg. for most of the orbits. Since beginning of January 2005 an increase of the yaw angle error is noted. This is due to an enhanced solar activity which could have influenced the air drag and disturbing torques on the satellite. In the delivered products, the combined kp and yaw-error flag was set, allowing the users to reject the low quality measurements.

Calibration performance

- Calibration data from Transponder are regularly acquired and archived for re-processing. The TOSCA (Tool for Scatterometer CALibration) project is ongoing. The oSAT is scheduled at the end of April 2005.
- Due to the regional mission scenario the calibration performances over the Brazilian rain forest are not available because that area is not covered by the ESA ground station. The chance to install a new station to cover the calibration site is under investigation as well as the possibility to use stable ice area in Greenland to monitor the instrument calibration.

- The Ocean Calibration monitoring is performed by ECMWF. Compared to cycle 100 the bias level stayed stable. Average bias level is around -0.30 dB, which is 0.20 dB less negative than for nominal data in 2000.

Instrument performance

- During the cycle 101 the mean power decrease has been regular with a negative slope of around 0.16 dB per cycle, it was 0.08 dB/cycle for cycle 100.
- The evolution of the noise power during the cycle 101 was stable. The daily average noise power for the Fore and Aft beam was around 1.7 ADC (I) and around 1.6 ADC (Q) respectively. For the Mid beam the noise is not measurable.
- During the cycle 101 the Doppler compensation evolution was stable. The CoG of the compensated signal was around 0 Hz for the Fore and Aft antenna and around 200 Hz for the Mid antenna. The standard deviation of the CoG was around 1500 Hz for the Fore and Aft antenna and around 2700 Hz for the Mid antenna. The small increase (about 100 Hz) in the evolution of the CoG at the beginning of January 2005 for the Mid beam is due to an increase of the solar activity that caused a slight degradation in the satellite attitude.

Product performance

During cycle 101 data was received between 21:04 UTC 13 December 2004 and 19:46 UTC 17 January 2005. No data was received for the 6-hourly data batches between 12 UTC and 18 UTC 14 December 2004, for 00 UTC 15 December 2004, between 00 UTC and 06 UTC 17 December 2004 (AMI internal test), and for the period from 06 UTC 26 December 2004 to 18 UTC 28 December 2004 (IDHT and onboard anomaly). In general, largest volumes (typically above 10,000) were received for 6-hourly data batches centered at 00 UTC and 12 UTC (Note from ESRIN: this is due to acquisition on West Freugh station that has some overlap with Kiruna or Maspalomas Station).

Compared to cycle 100, the comparison with ECMWF first-guess (FG) fields showed an increased relative standard deviation (from 1.59 m/s to 1.68 m/s). It is related to seasonal variations of the non-global data coverage, and a similar trend was observed for 2003. The relative bias has become more negative (from -0.65 m/s to -0.80 m/s). The negative bias for CMOD5 winds has grown somewhat as well (from -0.10 m/s to -0.19 m/s). Relative bias levels are comparable to those for 2000; the relative standard deviation is larger.

The PCS geophysical monitoring reports a wind speed bias (18 or 24 hour forecast vs UWI) around 0.8m/s and a wind speed standard deviation around 2.0 m/s. For the wind direction deviation the 98% of the nodes have directions in agreement with the meteorological forecast.

Those values confirm the analysis from the ECMWF.

2 Calibration Performances

The calibration performances are estimated using three types of target: a man made target (the transponder) and two natural targets (the rain forest and the ocean). This approach allow us to design the correct calibration using a punctual but accurate information from transponders and an extended but noisy information from rain forest and ocean for which the main component of the variance comes from the geophysical evolution of the natural target and from the backscattering models used. These aspects are in the calibration performance monitoring philosophy. The major goals of the calibration monitoring activities are the achievement of a “flat” antenna pattern profile and the assurance of a stable absolute calibration level.

2.1 Gain Constant over transponder

One gain constant is computed per transponder per beam from the actual and simulated two-dimensional echo power, which is given as a function of the orbit time and range time. This parameter clearly indicates the difference between “real instrument” and the mathematic model. In order to acquire data over the transponder the Scatterometer must be set in an appropriate operational mode defined as “Calibration Mode”. Since January 2001 with the operations in Zero Gyro Mode (ZGM) the satellite attitude is not stable as it was in the nominal Yaw Steering Mode (YSM). In particular there is a non-predictable variation of the yaw error angle along the orbit. For that reason the gain constant data computed by the CALPROC processor, that assumes a stable orbit, are meaningless and a new calibration processor is under development. In the mean time, data from the Transponder are still acquired and archived for future re-processing. The reprocessed gain constants will be provided in this section when available. For the gain constant computed during the nominal YSM please refer to the Scatterometer cyclic report cycle 60.

2.2 Ocean Calibration

The average sigma0 bias levels (compared to simulated sigma0's based on ECMWF model FG winds) stratified with respect to antenna beam, ascending or descending track and as function of incidence angle (i.e. across-node number) is displayed in Figure 1.

Bias levels are very similar to those during cycle 100. Inter-node and inter-beam dependencies are small. Average bias level is around -0.30 dB, which is 0.20 dB less negative than for nominal data in 2000.

The data volume of descending and ascending tracks is similar.

FIGURE 1 ERS-2 Scatterometer Ocean Calibration cycle 100. Ratio of $\langle \sigma_0^{0.625} \rangle / \langle CMOD4(First\ Guess)^{0.625} \rangle$ converted in dB for the fore beam (solid line), mid beam (dashed line) an aft beam (dotted line), as a function of incidence angle for descending and ascending tracks. The thin lines indicate the error bars on the estimated mean. First-guess winds are based on the in time closest (+3h, +6h, +9h, or +12h) T511 forecast field, and are bilinearly interpolated in space.

2.3 Gamma-nought over the Brazilian rain forest

Although the transponders give accurate measurements of the antenna attenuation at particular points of the antenna pattern, they are not adequate for fine tuning across all incidence angles, as there are simply not enough samples. The tropical rain forest in South America has been used as a reference distributed target. The target at the working frequency (C-band) of ERS-2 Scatterometer acts as a very rough surface, and the transmitted signal is equally scattered in all directions (the target is assumed to follow the isotropic approximation). Consequently, for the angle of incidence used by ERS-2 Scatterometer, the normalized backscattering coefficient (sigma nought) will depend solely on the surface effectively seen by the instrument:

$$S^0 = S \cdot \cos \theta$$

With this hypothesis it is possible to define the following formula:

$$\gamma^0 = \frac{\sigma^0}{\cos \theta}$$

Using the above equation, the gamma nought backscattering coefficient over the rain forest is independent of the incident angle, allowing the measurements from each of the three beams to be compared. The test area used by the PCS is located between 2.5 degrees North and 5.0 degrees south in latitude and 60.5 degrees West and 70.0 degrees West in longitude. That area is actually not covered by the Regional mission scenario (since cycle 86 onwards) and therefore the calibration monitoring activity over the Brazilian rain forest is suspended because no data are available. The chance to continue the monitoring activity with a new receiving station covering the Brazilian rain forest is under investigation. The following paragraphs will report on the results when data will be available.

2.4 Antenna pattern: Gamma-nought as a function of elevation angle

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason the antenna patterns in function of the elevation angle have not been computed.

2.5 Antenna pattern: Gamma-nought as a function of incidence angle

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason the antenna patterns in function of the incidence angle have not been computed.

2.6 Gamma nought histograms and peak position evolution

As the gamma nought is independent from the incidence angle, the histogram of gamma nought over the rain forest is characterized by a sharp peak. The time-series of the peak position gives some information on the stability of the calibration. This parameter is computed by fitting the histogram with a normal distribution added to a second order polynomial:

$$F(x) = A_0 \cdot \exp\left(-\frac{z^2}{2}\right) + A_3 + A_4 \cdot x + A_5 \cdot x^2$$

where: $z = \frac{x - A_1}{A_2}$

The parameters are computed using a non linear least square method called “gradient expansion”. The position of the peak is given by the maximum of the function F(x). The histograms are computed weekly (from Monday to Sunday) for each antenna individually “Fore”, “Mid” and “Aft” and for ascending and descending passes with a bin size of 0.02 dB. Due to the regional mission scenario data over the Brazilian rain forest are not available and the histograms have not been computed. For the time series since the beginning of the mission please refer to the Scatterometer cyclic report cycle 86.

2.7 Gamma nought image of the reference area

Due to the regional mission scenario data over the Brazilian rain forest are not available and the histograms have not been computed.

2.8 Sigma nought evolution

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason none update has been done to the sigma nought evolution time series. For the time series since the beginning of the mission until June 2003 please refer to the Scatterometer cyclic report cycle 86.

2.9 Antenna temperature evolution over the Rain Forest

Due to the regional mission scenario data over the Brazilian rain forest are not available. For the time series since the beginning of the mission please refer to the Scatterometer cyclic report cycle 86.

3 Instrument performance

The instrument status is checked by monitoring the following parameters:

- Centre of Gravity (CoG) and standard deviation of the received signal spectrum after the on-ground Doppler Compensation filter. This parameter is useful for the monitoring of the orbit stability, the performances of the Doppler compensation filter, the behavior of the yaw steering mode and the performances of the devices in charge for the satellite attitude (e.g. gyroscopes, Earth sensor, Sun sensor).
- Noise power I and Q channel.
- Internal calibration pulse power.

The latter is an important parameter to monitor the transmitter and receiver chain, the evolution of pulse generator, the High Power Amplifier (HPA), the Traveling Wave Tube (TWT) and the receiver. These parameters are extracted daily from the UWI products and averaged. The evolution of each parameter is characterized by a least square line fit. The coefficients of the line fit are printed in each plot.

3.1 Centre of gravity and standard deviation of received power spectrum

The Figure 2 shows the evolution of the two parameters for each beam since the beginning of the ERS-2 mission and Figure 3 shows the same evolution only for the cycle101.

The tendency during the nominal Yaw Steering Mode (YSM) period (beginning of the mission since the operation with the Mono Gyro (MGM) Attitude On-board Control System (AOCS) configuration on 7th February 2000) is a small and regular increase of the Centre of gravity (CoG) of received spectrum for the three antennae. During the YSM, two small changes can be detected in the CoG evolution. The first change is from 24th, January 1996 to 14th, March 1996, the second one is from 14th February 1997 to 22nd April 1997. The reason was a change in the pointing subsystem (DES reconfiguration) side B instead of side A after a depointing anomaly (see table 1 for the list of the all AOCS depointing anomaly occurred during the ERS-2 mission). During these periods side B was switched on. It is important to note that during the first time a clear difference in the CoG of the received spectrum is present only for the Fore antenna (an increase of roughly 100 Hz) while during the second time the change has affected all the three antennae (roughly an increase of 200 Hz, 50 Hz and 50 Hz for the fore, mid and aft antenna respectively).

At the beginning of 2000 the nominal 3-gyros AOCS configuration (plus one Digital Earth Sensor -DES, and one Digital Sun Sensor -DSS and backups) was no more considered safe because 3 of the six gyros on-board were out of order or very noisy. For that reason the MGM was implemented as default piloting mode. The MGM configuration was designed to pilot the ERS-2 using only one gyro plus the DES and the DSS modules. Scope of ZGM configuration was to extend the satellite lifetime by using the available gyros one at the time.

With the MGM, an increase of roughly 200 Hz was observed at the end of the qualification period. After the AOCS commissioning phase this parameter further evolved within the nominal range with a negligible impact on the data quality.

In MGM configuration, the gyro 5 was used until 7th October 2000 when it failed. From 10th October 2000 to 24th October 2000 the gyro 6 was used. This explains the decrease of roughly 100Hz in the CoG of the received spectrum. From 25th October 2000 to 17th January 2001 the gyro 1 was used to pilot the ERS-2 satellite. On 17th January 2001 the AOCS was upgraded. The new configuration allows piloting the satellite without gyroscopes. Unfortunately a failure of the Digital Earth Sensor (DES A-side) caused ERS-2 to enter in Safe-Mode on the same day. On 25th January 2001 gyro #1 also failed.

Satellite attitude was recovered on 5th February 2001 with a coarse attitude control mode (EBM). During the period of safe mode the spacecraft had drifted out of the nominal dead band by some 30 Km. The nominal orbit was reached on 6th February 2001.

The EBM mode had a strong negative impact on the Scatterometer data quality and the dissemination of data products to end users was discontinued.

After that a series of AOCS upgrades has been implemented in order to improve the satellite attitude: on 30th March 2001 the Yaw steering law was re-introduced into the piloting function and on 7th June 2001 the Zero Gyro Mode (ZGM) has been implemented as nominal piloting mode. In ZGM the satellite attitude had an improvement in particular for the pitch and yaw error angle. This explains the reduction of the fluctuation in the received signal.

The CoG returns within its nominal value in February 2003 when the new ERS Scatterometer ground processor (ESACA) was put in operation (only for validation purposes) in Kiruna station. ESACA is able to compensate for errors in satellite attitude and to produce calibrated sigma noughts.

The evolution of the standard deviation of the CoG of the received spectrum was stable during the YSM phase. Small peaks are related with the events listed in Table 2. In MGM the evolution was within the nominal range while for the initial phase of the ZGM the performance was strong degraded. This because the on-ground Doppler filters was not able to compensate for the satellite degraded attitude. The introduction of the ESACA processor in February 2003 cured the problem.

TABLE 1 ERS-2 Scatterometer AOCS depointing anomaly list

Start of the anomaly			End of the anomaly			Remarks
24 th January	1996	9:10 a.m.	26 th January	1996	6:53 p.m.	AOCS depointing anomaly
14 th February	1997	1:25 a.m.	15 th February	1997	3:44 p.m.	AOCS depointing anomaly
3 rd June	1998	2:43 p.m.	6 th June	1998	12:47 a.m.	AOCS depointing anomaly
1 st September	1999	8:50 a.m.	2 nd September	1999	1:28 a.m.	
7 th October	2000	4:38 p.m.	10 th October	2000	4:49 p.m.	depointing anomaly gyro 5 failure
24 th October	2000	4:05 p.m.	25 th October	2000	12:05 p.m.	depointing anomaly gyro 6 failure
17 th January	2001		5 th February	2001		gyro 1 failure Satellite in safe mode

TABLE 2 ERS-2 Scatterometer anomalies in the Doppler Compensation monitoring

Date start	Year	Date stop	Year	Reason
26 th September	1996	27 th September	1996	Missing on-board Doppler coefficient (after cal. DC converter test period)
6 th June	1998	7 th June	1998	No Yaw Steering Mode (after depointing anomaly)
2 nd December	1998	3 rd December	1998	Missing on-board Doppler coefficients (after AMI anomaly number 228)
16 th February	2000	17 th February	2000	Fine Pointing Mode (FPM) (due to AOCS mono-gyro qualification period)
14 th April	2000	14 th April	2000	Fine Pointing Mode (FPM)
5 th July	2000	5 th July	2000	Fine Pointing Mode (FPM) after instrument switch-on
27 th September	2000	27 th September	2000	Fine Pointing Mode (FPM) to upload AOCS software patch
2 nd November	2000	2 nd November	2000	Fine Pointing Mode (FPM)
5 th December	2000	6 th December	2000	Fine Pointing Mode (FPM) due to orbital manoeuvre
6 th February	2001	30 th March	2001	Extra Backup Mode (EBM) coarse attitude control
30 th March	2001	17 th June	2001	ZGM-EBM coarse attitude control
17 th June	2001	21 st August	2003	ZGM phase. Error in yaw angle not corrected in the ground segment processor. Data shall be reprocessed with ESACA.
24 th March	2004	24 th March	2004	Fine Pointing Mode (FPM) due to orbital manoeuvre
25 th October	2004	27 th October	2004	Series of orbital manoeuvres (OCM and FPM)
10 th November	2004	11 th November	2004	Intense geomagnetic storm

During the cycle 101 the Doppler compensation evolution was very stable (see Figure 3). The CoG of the compensated signal was around 0 Hz for the Fore and Aft antenna and around 200 Hz for the Mid antenna. The standard deviation of the CoG was around 1500 Hz for the Fore and Aft antenna and around 2700 Hz for the Mid antenna.

The small increase (about 100 Hz) in the evolution of the CoG at the beginning of January 2005 for the Mid beam is due to an increase of the solar activity that caused a slight degradation in the satellite attitude. The small dip on the CoG evolution on 26th and 27th December 2004 is due to a small amount of data used for the daily statistics (AMI unavailability).

ERS-2 WindScatterometer: DOPPLER COMPENSATION Evolution (UWI)

Least-square poly. fit fore beam Center of gravity = $-114.2 + (0.0522) \cdot \text{day}$ Standard Deviation = $4337.3 + (-0.418) \cdot \text{day}$
 Least-square poly. fit mid beam Center of gravity = $-789.9 + (0.3166) \cdot \text{day}$ Standard Deviation = $5852.3 + (-0.686) \cdot \text{day}$
 Least-square poly. fit aft beam Center of gravity = $-354.9 + (0.1411) \cdot \text{day}$ Standard Deviation = $4558.1 + (-0.484) \cdot \text{day}$

FIGURE 2 ERS-2 Scatterometer: Centre of Gravity and standard deviation of received power spectrum since the beginning of the mission.

ERS-2 WindScatterometer: DOPPLER COMPENSATION Evolution (UWI)

Least-square poly. fit fore beam Center of gravity = $48.396 + (-0.059) \cdot \text{day}$ Standard Deviation = $1466.0 + (-0.187) \cdot \text{day}$
 Least-square poly. fit mid beam Center of gravity = $265.67 + (0.3116) \cdot \text{day}$ Standard Deviation = $2725.0 + (-1.447) \cdot \text{day}$
 Least-square poly. fit aft beam Center of gravity = $-44.40 + (0.3882) \cdot \text{day}$ Standard Deviation = $1474.2 + (-0.254) \cdot \text{day}$

FIGURE 3 ERS-2 Scatterometer: Centre of Gravity and standard deviation of received power spectrum during the cycle 101.

3.2 Noise power level I and Q channel

The results of the monitoring are shown in Figure 4 (long-term) and Figure 5 (cycle 101). The first set of three plots presents the noise power evolution for the I channel while the second set shows the Q channel. From the plots one can see that the noise level is more stable in the I channel than in the Q one. The I and Q receivers are inside the same box and any external interference should affect both channel. The fact that the receivers are closer to the ATSR-GOME electronics could have some impact but there is no clear explanation on that behavior.

From 5th December 1997 until November 1998 some high peaks appear in the plots. These high values for the daily mean are due to the presence for these special days of a single UWI product with an unrealistic value in the noise power field of its Specific Product Header. The analysis of the raw data used to generate these products lead in all cases to the presence of one source packet with a corrupted value in the noise field stored into the source packet Secondary Header. The reason why noise field corruption is beginning from 5th December 1997 and last until November 1998 is at present unknown. It is interesting to note that at the beginning of December 1997, we started to get as well the corruption of the Satellite Binary Times (SBTs) stored in the EWIC product. The impact in the fast delivery products was the production of blank products starting from the corrupted EWIC until the end of the scheduled stop time. A change in the ground station processing in March 1998 overcame this problem. Since 9th August 1998 until March 2000 some periods with a clear small instability in the noise power have been recognized, Table 3 gives the detailed list.

TABLE 3 ERS-2 Periods with instability in the noise power

Start date	Stop date	Year
9 th August	26 th October	1998
29 th November	6 th December	1998
23 rd December	24 th December	1998
7 th June	10 th June	1999
17 th August	22 nd August	1999
8 th September	9 th September	1999
3 rd October	8 th October	1999
16 th October	18 th October	1999
26 th October	28 th October	1999
25 th December	2 nd January	2000
10 th February	11 th February	2000
19 th March	26 th March	2000

To better understand the instability of the noise power the PCS has carried out investigations in the Scatterometer raw data (EWIC) to compute the noise power with more resolution. The result is that for the orbits affected by the instability the noise power had a decrease of roughly 0.7 dB for the fore and aft signals and a decrease of roughly 0.6 dB in the mid beam case (see the report for the cycle 42). The decrease of the noise power during the orbits affected by the instability is comparable with the decrease of the internal calibration level that occurred during the same orbits. The reason of this instability (linked to the AMI anomalies) is still unknown. On 28th February 2003 the Scatterometer receiver gain has been increased by 3 dB to optimize the usage of the on-board ADC converter. This explains the increase of the noise for the Fore and Aft beam channel. For the mid beam channel the noise still remains not measurable. The evolution of the noise power during the cycle 101 was stable (see Figure 5). The daily average for the Fore and Aft beam noise is around 1.7 ADC (I) and around 1.6 ADC (Q) respectively. For the Mid beam the noise is not measurable. The small dip on the

Noise evolution on 26th and 27th December 2004 is due to a small amount of data used for the daily statistics (AMI unavailability).

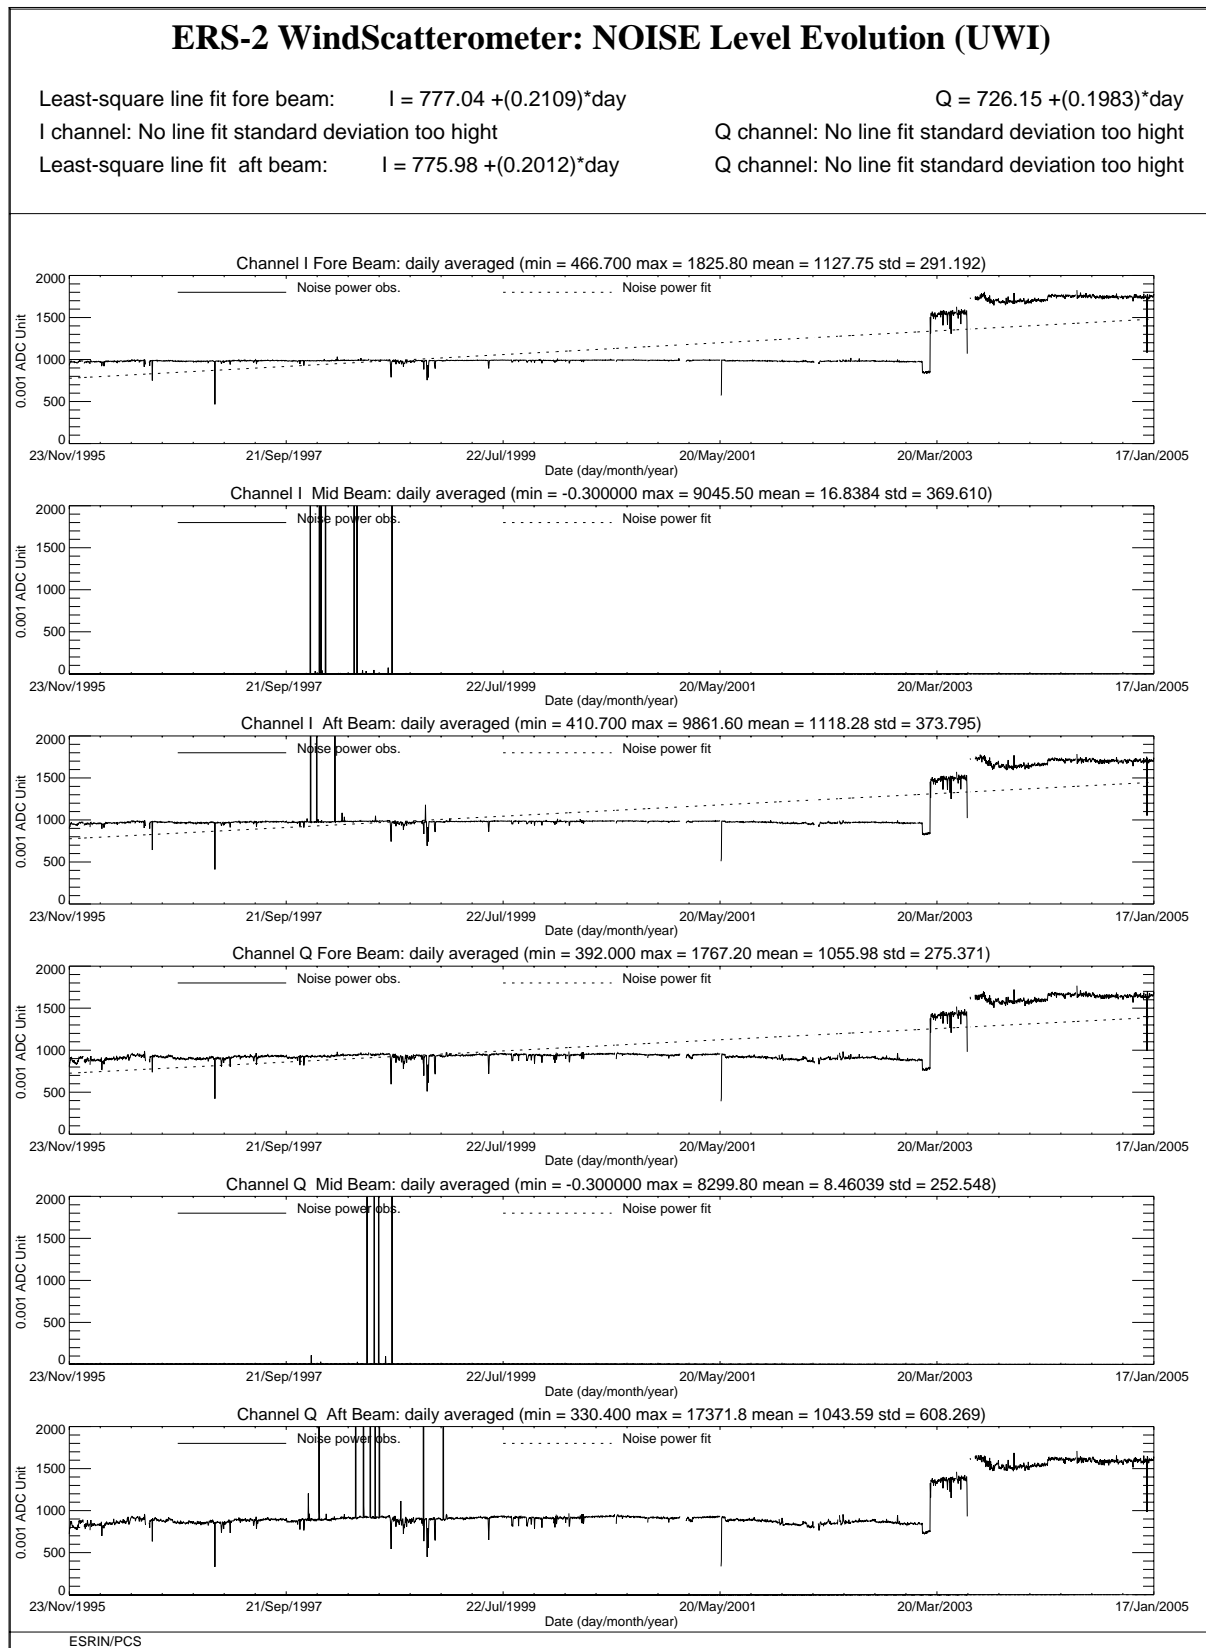

FIGURE 4 ERS-2 Scatterometer: noise power I and Q channel since the beginning of the mission.

ERS-2 WindScatterometer: NOISE Level Evolution (UWI)

Least-square line fit fore beam: $I = 1740.5 + (0.4200) \cdot \text{day}$ $Q = 1635.8 + (0.6609) \cdot \text{day}$
 Least-square line fit mid beam: $I = 0.0353 + (-0.000) \cdot \text{day}$ $Q = 0.0021 + (0.0018) \cdot \text{day}$
 Least-square line fit aft beam: $I = 1698.7 + (0.4584) \cdot \text{day}$ $Q = 1587.2 + (0.7073) \cdot \text{day}$

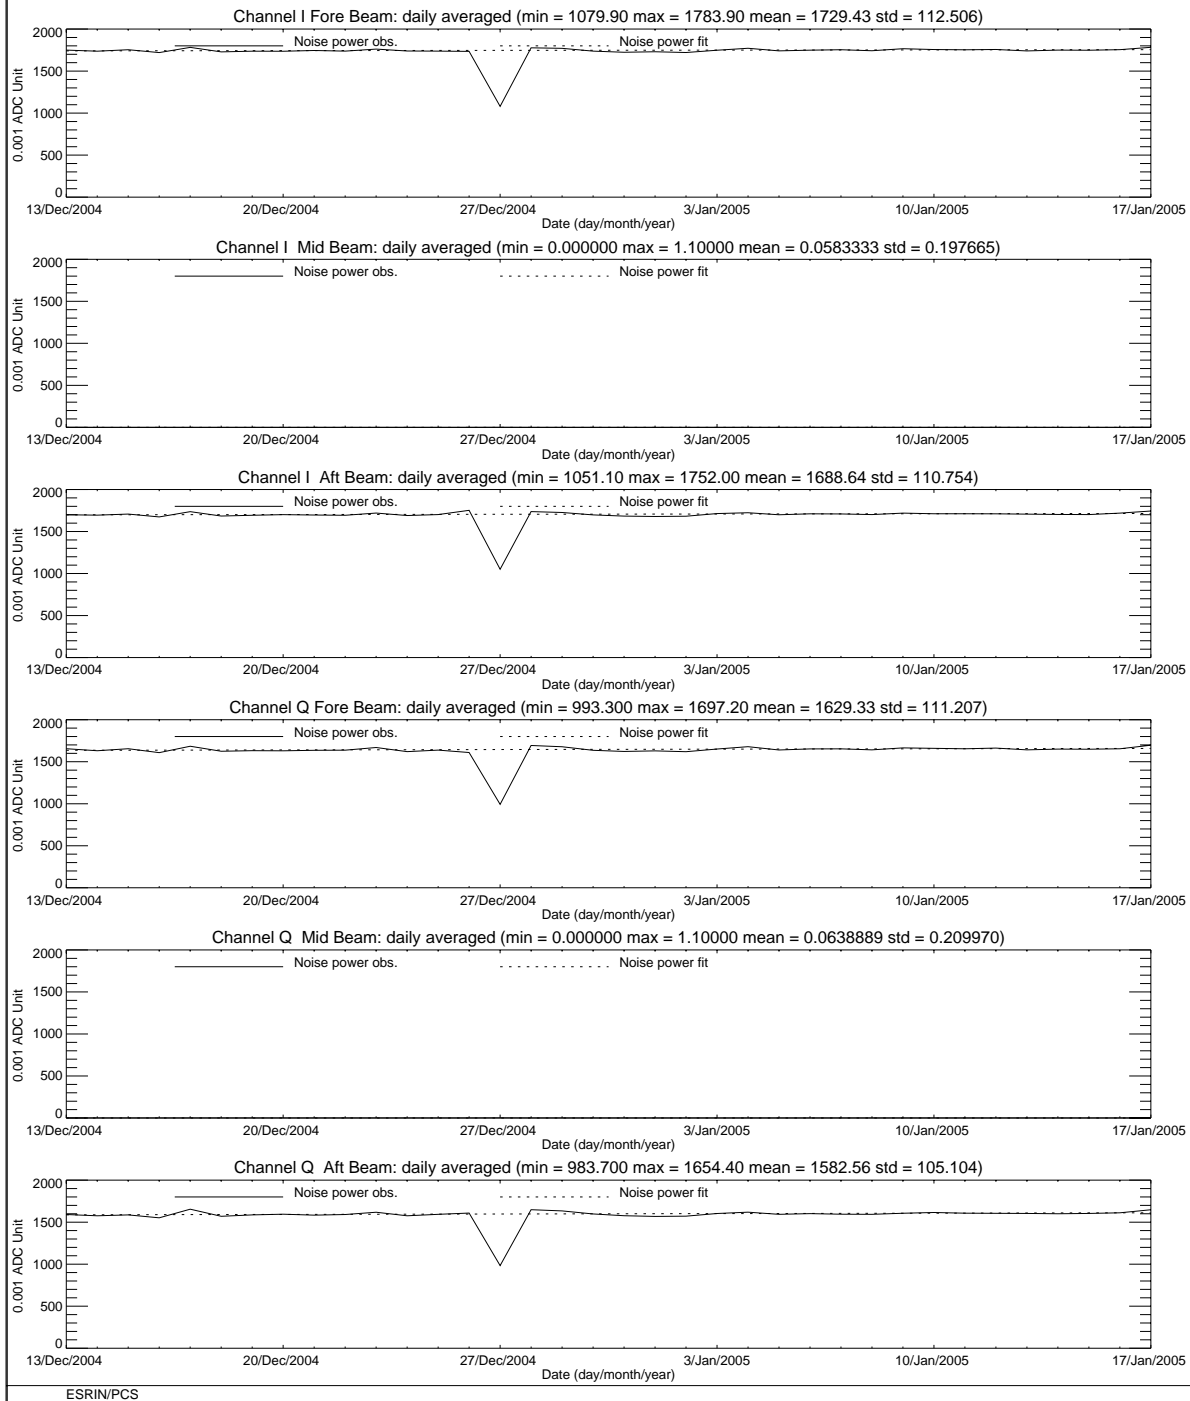

FIGURE 5 ERS-2 Scatterometer: noise power I and Q channel for cycle 101.

3.3 Power level of internal calibration pulse

For the internal calibration level, the results are shown in Figure 6 (long-term) and Figure 7 (cycle 101). The high value of the variance in the fore beam until August, 12th 1996 is due to the ground processing. In fact all the blank source packets ingested by the processor were recognized as Fore beam source packets with a default value for the internal calibration level. The default value was applicable for ERS-1 and therefore was not appropriate for ERS-2 data processing. On August 12th, 1996 a change in the ground processing LUT overcame the problem. Since the beginning of the mission a power decrease is detected. The power decrease is regular and affects the AMI when it is working in wind-only mode, wind/wave mode and image mode indifferently. The average power decrease is around 0.08 dB per cycle (0.0022 dB/day) and is clearer after August, 6th 1996 when the calibration subsystem has been changed. The reason of the power decrease is because the TWT is not working in saturation, so that a variation in the input signal is visible in the output. The variability of the input signal can be two-fold: the evolution of the pulse generator or the tendency of the switches between the pulse generator and the TWT to reset themselves into a nominal position. These switches were set into an intermediate position in order to put into operation the Scatterometer instrument (on 16th November 1995). To compensate for this decrease, on 26th October 1998 (cycle 37) 2.0 dB were added to the Scatterometer transmitted power and on 4th September 2002 (cycle 77) were added 3.0 dB. On 28th February 2003 (cycle 82) the Scatterometer receiver gain was increased by 3 dB to improve the usage of the on-board ADC converter. These events are clearly displayed by the large steps show in Figure 6.

Since 9th August 1998 until March 2000 the internal calibration level shows instability after an AMI or platform anomaly (see reports from cycle 35 to cycle 52). This instability is very well correlated with the fluctuations observed in the noise power. On 13th July 2000 a high peak (+3.5 dB) was detected in the transmitted power. This event has been investigated deeply by PCS and ESOC. The results of the analysis are reported in the technical note “ERS-2 Scatterometer: high peak in the calibration level” available in the PCS. The high transmitted power was detected after an arcing event which occurred inside the HPA. After that event the transmitted power had an average increase of roughly 0.14 dB.

During the cycle 101 the mean power decrease has been regular with a negative slope of around 0.16 dB per cycle, it was 0.08 for cycle 100. The variation on the internal calibration evolution on 26th and 27th December 2004 is due to the small amount of data used for the daily statistics (IDHT anomaly and AMI unavailability).

ERS-2 WindScatterometer: Internal CALIBRATION Level Evolution (UWI)

4 Products performance

The PCS carries out a quality control of the winds generated from the WSCATT data. External contributions to this quality control (from ECMWF) are also reported in this chapter.

4.1 Products availability

One of the most important points in the monitoring of the products performance is their availability. The Scatterometer is a part of ERS payload and it is combined with a Synthetic Aperture Radar (SAR) into a single Active Microwave Instrument (AMI). The SAR users requirements and the constraints imposed by the on-board hardware (e.g. amount of data that can be recorded in the on-board tape) set rules in the mission operation plan.

The principal rules that affected the Scatterometer instrument data coverage are:

- Over the Ocean the AMI is in wind/wave mode (Scatterometer with small SAR imaggettes acquired every 30 sec.) and the ATSR-2 is in low rate data mode.
- Over the Land the AMI is in wind only mode (only Scatterometer) and the ATSR-2 is in high rate mode. (Due to on board recorder capacity, ATSR-2 in high rate is not compatible with SAR wave imaggettes acquisitions.) This strategy preserves the Ocean mission.
- The SAR images are planned as consequence of users' request.

Moreover:

- since July 16th 2003 the ERS-2 Low Rate mission is continued within only the visibility of ESA ground stations over Europe, North Atlantic, the Arctic and western North America. The reason was the failure of both on-board tape recorders.

In order to maximize the data coverage, after the on-board tape recorder failure, an upgrade of the ERS ground segment acquisition scenario has been performed.

In that framework the following has been implemented:

- Since September 7th 2003 the ground station in Maspalomas, Gatineau and Prince Albert are acquiring and processing data for all the ERS-2 satellite passes within the station visibility (apart from passes for which other satellites have a higher priority).
- To further increase the wind coverage of the North Atlantic area, since December 8th, 2003 is operative a new ground Station in West Freugh (UK) and data from this new station are available to the user since mid January 2004. Due to its location, the West Freugh acquisitions have some overlap with those from three other ESA stations, Kiruna, Gatineau or Maspalomas. The station overlap depends on the relative orbit of the satellite. Consequentially, overlapping wind Scatterometer LBR data may be included in two products. Since the two products are generated at different ground stations the overlap may not be completely precise, with a displacement up to 12 Km and slight differences in the wind data itself.
- Since March, 3rd 2004, Matera station is acquiring low rate bit data for all the passes for which is planned a SAR acquisition. Some science data are produced and disseminated to users, Radar Altimeter data, Wave data and Scatterometer data are recorded on tapes and will be available off-line for re-processing. This means for the Scatterometer data coverage a very limited improvement due to the fact that are acquired only passes with some SAR activity.

- Since November 2004 a new acquisition station in Miami (US) is under qualification. This will let a full coverage of the Gulf of Mexico and part of the Pacific Ocean on the west Mexico coast. Fast delivery data has been disseminated since February 2005.

Figure 8 shows the AMI operational modes for cycle 101. Each segment of the orbit has different color depending on the instrument mode: brown for wind only mode, blue for wind-wave mode and green for image mode. The red and yellow colors correspond to gap modes (no data acquired). For cycle 101 the percentage of the ERS-2 AMI activity is shown in table 4. The values for the wind, wind-wave are slightly below the nominal range due to the AMI unavailability occurred during the cycle 101.

Since 25th February 2004 onwards the ATSR is operated again in High Rate over land.

TABLE 4 ERS-2 AMI activity (cycle 101)

Ami Mode	Ascending passes	Descending passes
Wind and Wind-Wave	87.41 %	79.75%
Image	2.81 %	12.48 %
Gap and others	9.78 %	7.77 %

Table 5 reports the major data lost due to the test periods, AMI and satellite anomalies or ground segment anomalies occurred after 6th August, 1996 (before that day for many times data were not acquired due to the DC converter failure).

TABLE 5 ERS-2 Scatterometer mission major data lost after 6th, August 1996

Start date	Stop Date	Reason
September 23 rd , 1996	September 26 th , 1996	ERS 2 switched off due to a test period
February 14 th , 1997	February 15 th , 1997	ERS 2 switched off due to a depointing anomaly
June 3 rd , 1998	June 6 th , 1998	ERS 2 switched off due to a depointing anomaly

FIGURE 8 ERS-2 AMI activity during cycle 101.

4.2 PCS Geophysical Monitoring

The routine analysis is summarized in the plots of figure 9; from top to bottom:

- the monitoring of the valid sigma-nought triplets per day.
- the evolution of the wind direction quality. The ERS wind direction (for all nodes and only for those nodes where the ambiguity removal has worked properly) is compared with the ECMWF forecast. The plot shows the percentage of nodes for which the difference falls in the range -90.0, +90.0 degrees.
- the monitoring of the percentage of nodes whose ambiguity removal works successfully.
- the comparison of the wind speed deviation: (bias and standard deviation) with the ECMWF forecast.

The results since August 6th, 1996 until the beginning of the operation with the Zero Gyro Mode (ZGM) in January 2001 can be summarized as:

- High quality wind products has been distributed since Mid March 1996 (end of calibration and validation phase)
- The number of valid sigma-nought distributed per day was almost stable with a small increase after June 29th, 1999 due to the dissemination in fast delivery of the data acquired in the Prince Albert station (Canada).
- The wind direction is very accurate for roughly 93% of the nodes, the ambiguity removal processing successfully worked for more than 90.0% of the nodes.
- The UWI wind speed shows an absolute bias of roughly 0.5 m/s and a standard deviation that ranges from 2.5 m/s to 3.5 m/s with respect to the ECMWF forecast.
- The wind speed bias and its standard deviation have a seasonal pattern due to the different winds distribution between the winter and summer season.
- Two important changes affect the speed bias plot.
- the first is on June 3rd, 1996 due to the switch from ERS-1 to ERS-2 data assimilation in the meteorological model.
- the second which occurred at the beginning of September 1997, is due to the new monitoring and assimilation scheme in ECMWF algorithms (4D-Var).
- Since 19th April 1999 two set of meteo-table (meteorological forecast centred at 00:00 and 12:00 of each day) are used in the ground processing. This allowed the processing of wind data with 18 and 24 hours meteorological forecast instead of the 18, 24, 30 36 hours forecast. The comparison between data processed with the 18-24 hours forecast instead of 30-36 hours forecast shown an increase in the number of ambiguity removed nodes with a neutral impact in the daily statistics.
- The mono-gyro AOCS configuration (see report for cycle 50) that was operative from 7th February 2000 to 17th January 2001 did not affect the wind data performance.

During the Zero Gyro Mode (ZGM) phase the dissemination of the fast delivery Scatterometer data to the users has been interrupted on 17th January 2001 due to degraded quality in sigma noughts and winds. The satellite attitude in ZGM is slightly degraded and the “old” ground processor was not able to produce calibrated data anymore. For that reason a re-design of the entire ground processing has been carried out and since August 21st 2003 the new processor named ERS Scatterometer Attitude Corrected Algorithm (ESACA) is operative in all the ESA ground station and data was redistributed to the user.

Although for a long period data was not distributed, the PCS has monitored the data quality (as shown in Figure 9) and the results during that period can be summarized as:

At the beginning of the ZGM (January 2001 - end July 2001) the number of valid nodes has clear drop from 190000 per day to 9000 per day. This because the satellite attitude was strong degraded and the received signal had a very high Kp figure (in particular for the far range nodes). For the valid nodes, due to no calibrated sigma nought, the quality of the wind was very poor, the distance from the cone was high and the wind speed bias was above 1.5 m/s.

At the end of July 2001 the ZGM has been tuned and the satellite attitude had an improvement. This explains the increase of the number of valid nodes (returned around the nominal level) and the improvements in the wind speed bias (around 0.5 m/s).

On 4th February 2003, a beta version of the new ESACA processor has been put in operation in Kiruna for validation and the monitoring of the data quality has been done only for the new ESACA data. The number of valid nodes slight decreased because Kiruna station process only 9 of 14 orbits per day. The wind speed direction deviation had a clear improvement because ESACA implements a new ambiguity removal algorithm (MSC) and the ambiguity removal rate is now stable at 100% (the MSC is able to remove ambiguity for all the nodes). The wind speed bias had a clear drop from 0.5 to -0.5 m/s. That value is closer to the nominal one (around -0.2 m/s). As reported in the previous cyclic reports the beta version of ESACA had some calibration problem for the near range nodes and this explains why the data quality does not match exactly the one obtained in the nominal YSM. That problem has been overcome with the final release of the ESACA processor put into operation on August 21st 2003. On June 22nd the failure of the on-board tape recorder discontinued the ERS global mission (see section 4.1) and this explains the low number of valid nodes available after that day.

The performances of ESACA winds delivered between August 2003 and September 2004 are affected by land contamination. Around costal zones many Sea nodes have a strong contribution of Land backscattering and the retrieved wind is not correct. An optimization of the Land/Sea flag in the ground processing has been carried out during the cycle 98. In the statistics computed by PCS on the fast delivered winds the Land contamination has been removed by using a refined Land/Sea mask. Also the ice contamination has been removed with a simple geographical filter. With these new setting the PCS statistics are very similar to the ones reported by ECMWF.

For cycle 101 the wind speed bias (UWI vs 18 or 24 hour forecast) is roughly 0.8 m/s (it was 0.6 m/s for cycle 100) and the speed bias standard deviation is around 2.0 m/s (it was 1.5 m/s for cycle 100). Those values are very similar to the ones computed by ECMWF. The fluctuation of the statistics is mainly due to the small amount of data available for each day. Due to the small amount of data available for the period 26th – 28th December 2004 (AMI and IDHT unavailability) the daily statistics shows some dips. On 11th – 13th January 2005, due to a problem in the meteorological file dissemination the PCS geophysical validation has not been computed.

The wind direction deviation was good. The 98% of the nodes have a wind direction in agreement with the meteorological forecast. The degradation of the wind direction performances noted in the period 15th November – 3rd December 2004 (cycle 100) is not present. This confirms that the ESACA ambiguity removal schema had worked properly. The performances of ESACA winds computed by ECMWF are given in section 4.3.

FIGURE 9 ERS-2 Scatterometer: wind products performance since the beginning of the mission.

FIGURE 10 ERS-2 Scatterometer: wind products performance for cycle 101.

4.3 ECMWF Geophysical Monitoring

The quality of the UWI product was monitored at ECMWF for cycle 101. Results were compared to those obtained from the previous cycle, as well for data received during the nominal period in 2000 (up to cycle 59). No corrections for duplicate observations were applied.

During cycle 101 data was received between 21:04 UTC 13 December 2004 and 19:46 UTC 17 January 2005. No data was received for the 6-hourly data batches between 12 UTC and 18 UTC 14 December 2004, for 00 UTC 15 December 2004, between 00 UTC and 06 UTC 17 December 2004 (AMI internal test), and for the period from 06 UTC 26 December 2004 to 18 UTC 28 December 2004 (IDHT anomaly). In general, largest volumes (typically above 10,000) were received for 6-hourly data batches centered at 00 UTC and 12 UTC (Note from ESRIN: this is due to acquisition on West Freugh station that has some overlap with Kiruna or Maspalomas Station).

Data is being recorded whenever within the visibility range of a ground station, leading for cycle 101 to a coverage of the North-Atlantic, part of the Mediterranean, the Gulf of Mexico, and to a small part of the Pacific north-west from the US and Canada (see Figure 12). After the data gap at 28 December 2004, the asymmetry between the fore and aft incidence angles showed the development of enhanced peaks. The k_p-yaw ESA flag had been set accordingly.

Compared to cycle 100, the comparison with ECMWF first-guess (FG) fields showed an increased relative standard deviation (from 1.59 m/s to 1.68 m/s). It is related to seasonal variations of the non-global data coverage, and a similar trend was observed for 2003. The relative bias has become more negative (from -0.65 m/s to -0.80 m/s). The negative bias for CMOD5 winds has grown somewhat as well (from -0.10 m/s to -0.19 m/s). Relative bias levels are comparable to those for 2000; the relative standard deviation is larger.

Ocean calibration shows that both bias levels and internode differences are small and stable.

The ECMWF assimilation system was not changed during cycle 101.

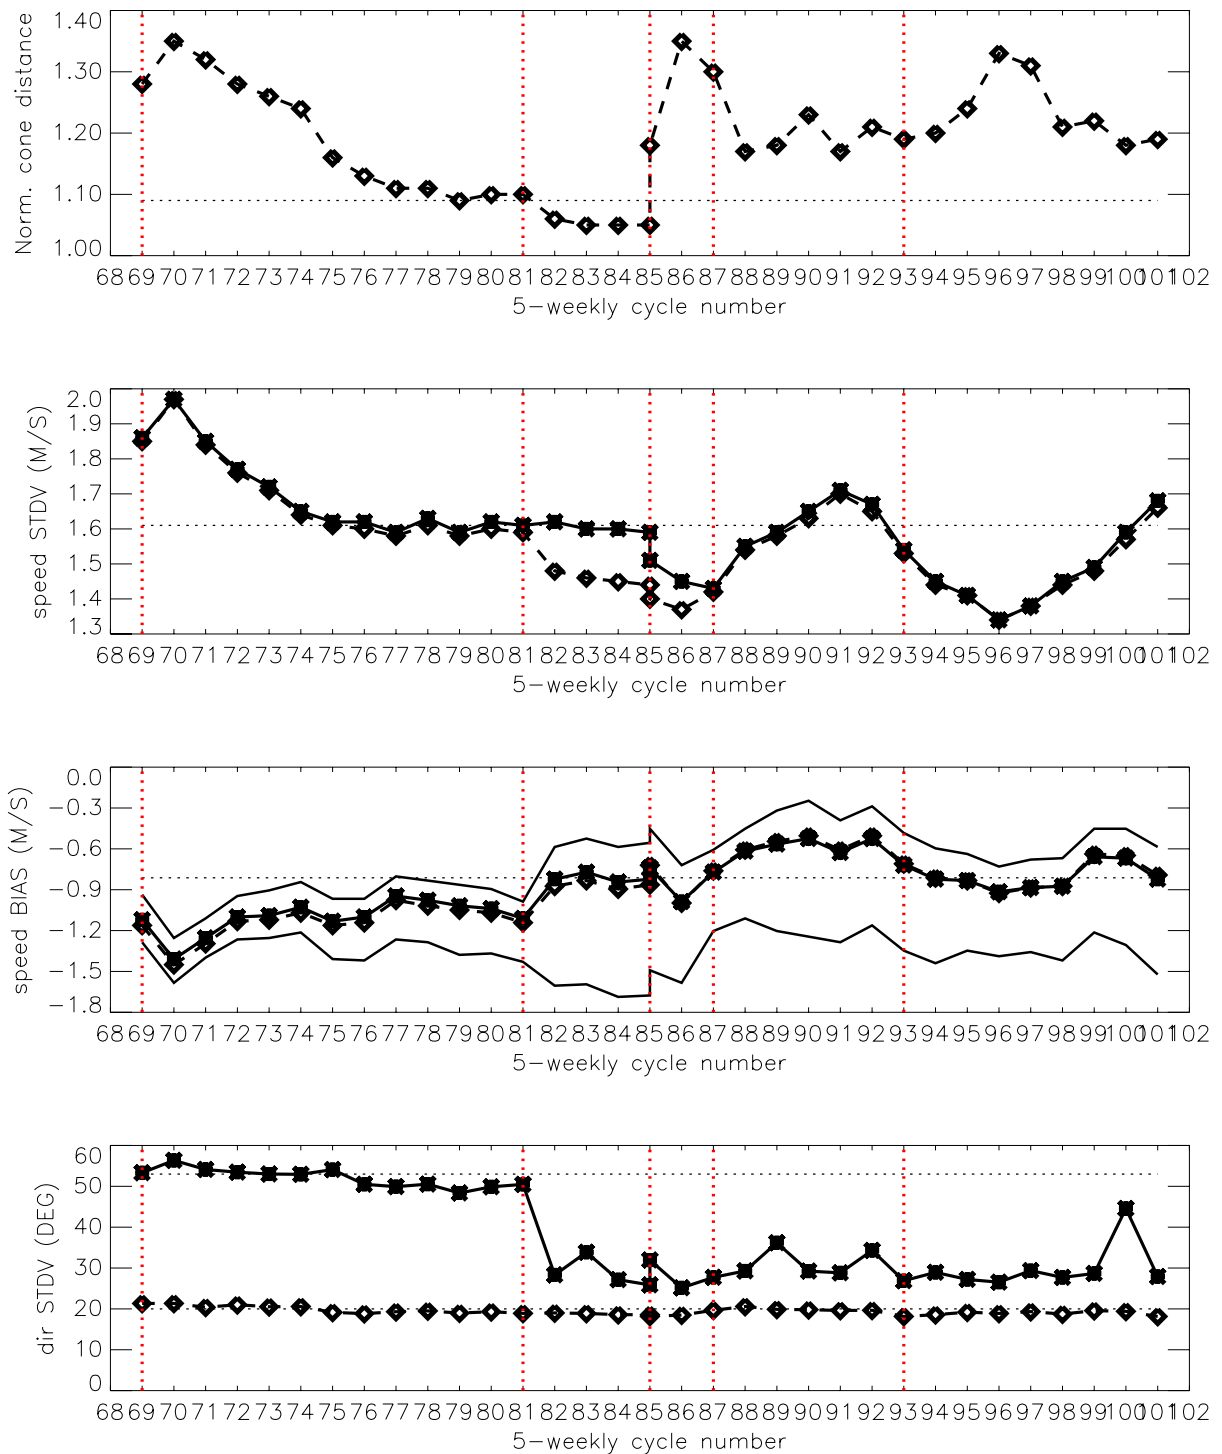

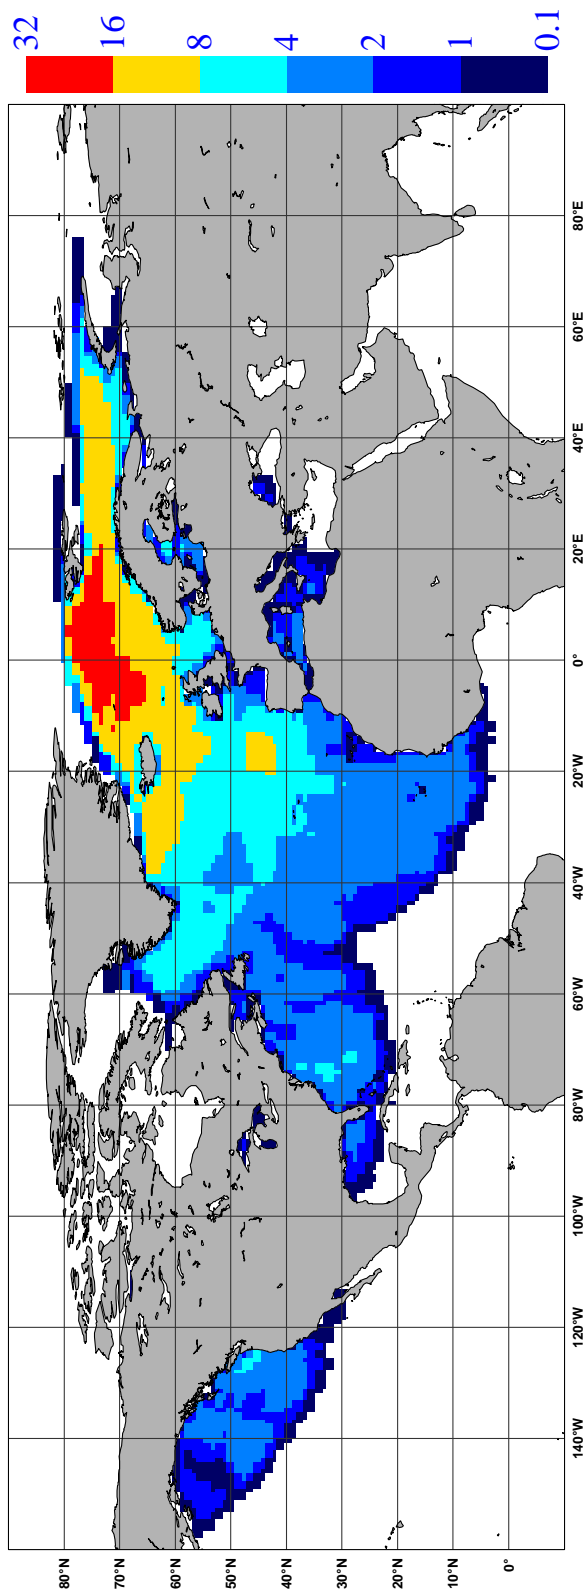

FIGURE 11 Evolution of the performance of the ERS-2 Scatterometer averaged over 5-weekly cycles from 12 December 2001 (cycle 69) to 17 January 2005 (end cycle 101) for the UWI product (solid, star) and de-aliased winds based on CMOD4(dashed, diamond). Results are based on data that passed the UWI QC flags. For cycle 85 two values are plotted; the first value for the global set, the second one for the regional set. Dotted lines represent values for cycle 59 (5 December 2000 to 17 January 2001),i.e. the last stable cycle of the nominal period. From top to bottom panel are shown the normalized distance to the one (CMOD4 only) the standard deviation of the wind speed compared to FG winds, the corresponding bias(for UWI winds the extreme inter-node averages are shown as well),and the standard deviation of wind direction compared to FG.

NOBS (ERS-2 UWI), per 12H, per 125km box
 average from 2004121400 to 2005011718 GLOB:3.61

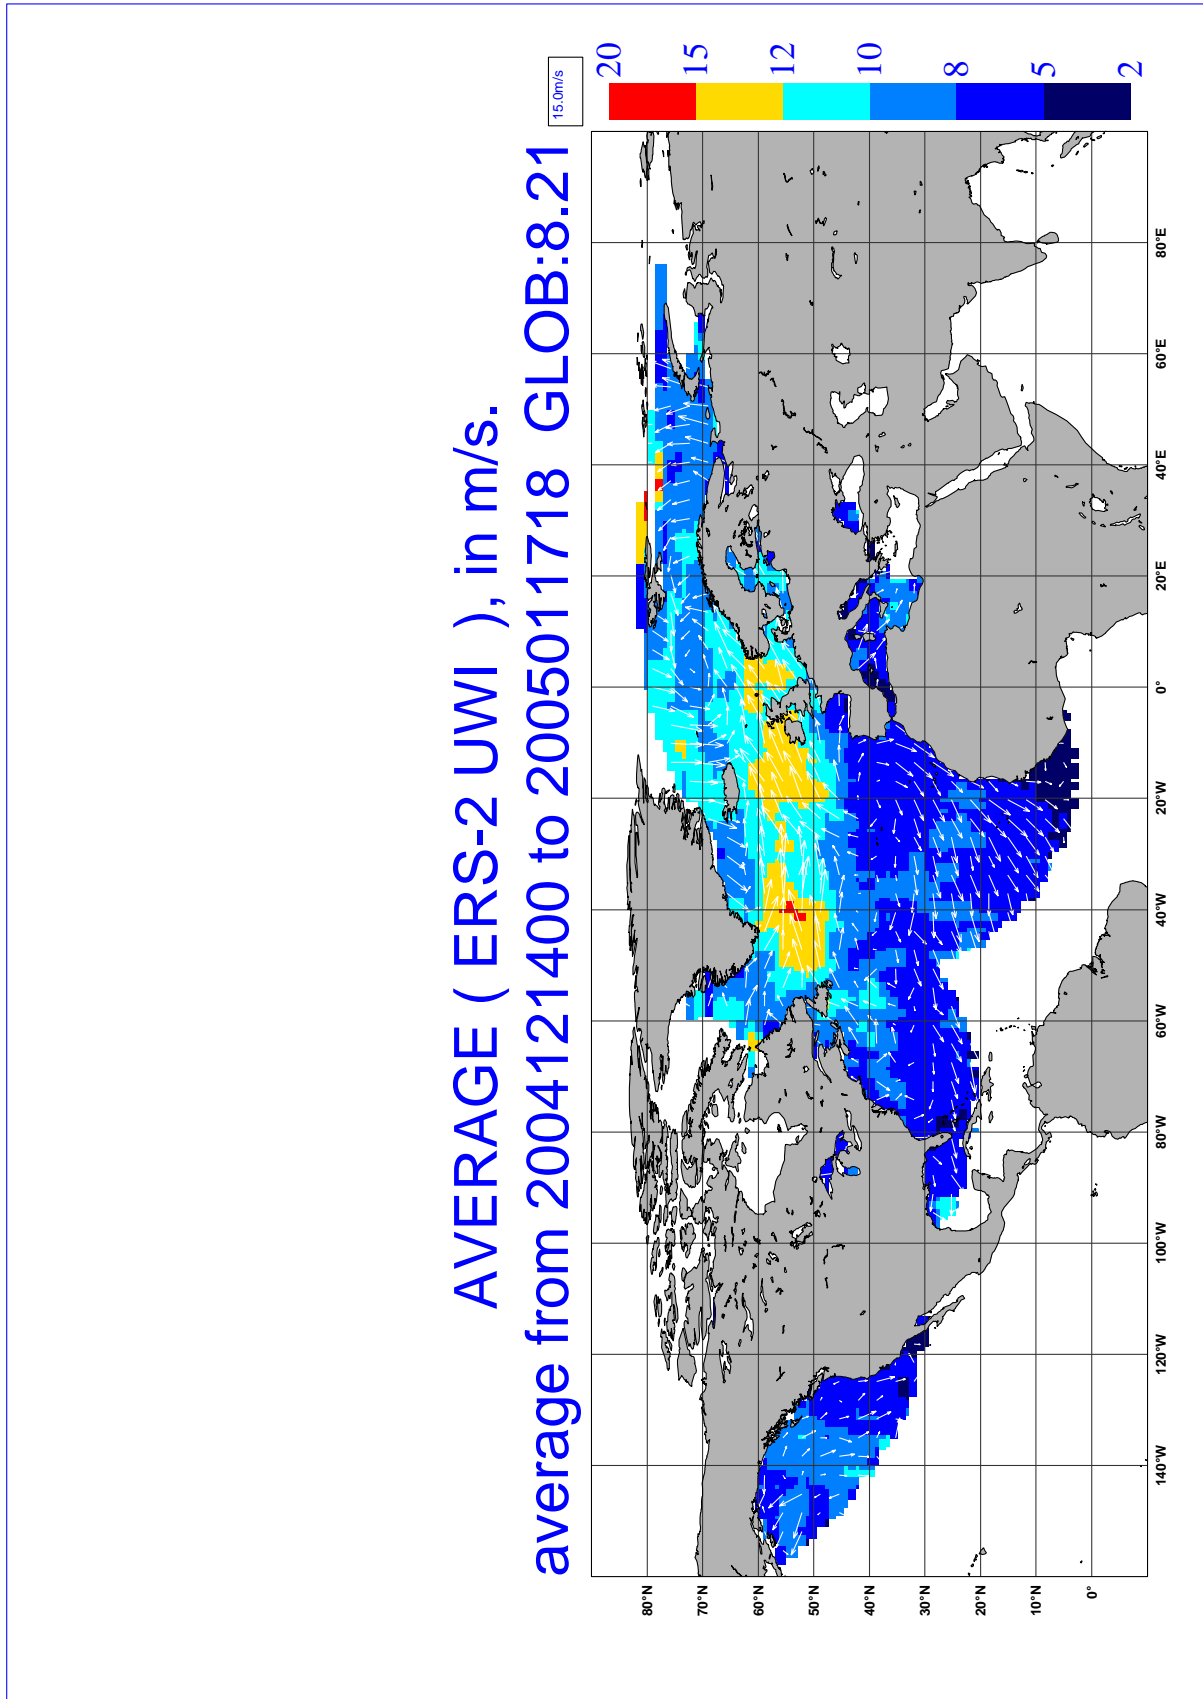

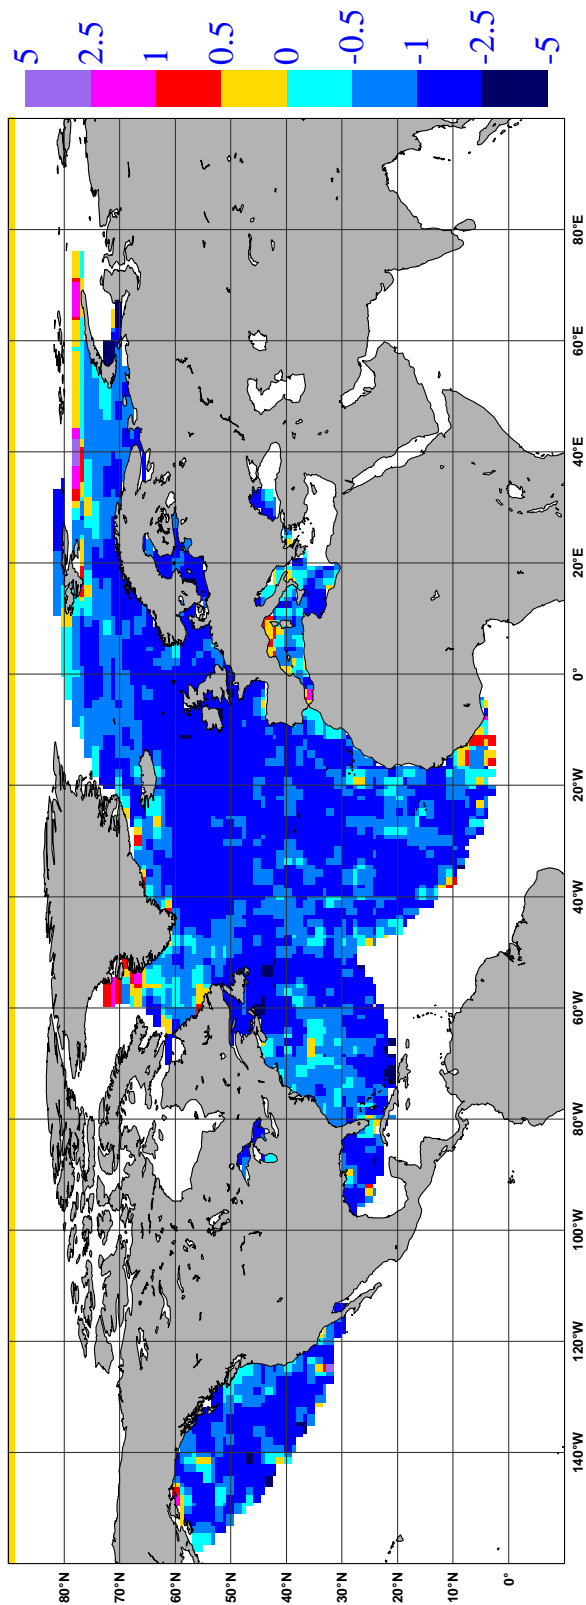

FIGURE 12 Average number of observations per 12H and per 125km grid box (top panel) and wind-climate (lower panel) for UWI winds that passed the UWI flags QC and a check on the collocated ECMWF land and sea-ice mask.

BIAS (ERS-2 UWI vs FIRST-GUESS), in m/s.
average from 2004121400 to 2005011718 GLOB:-1.06

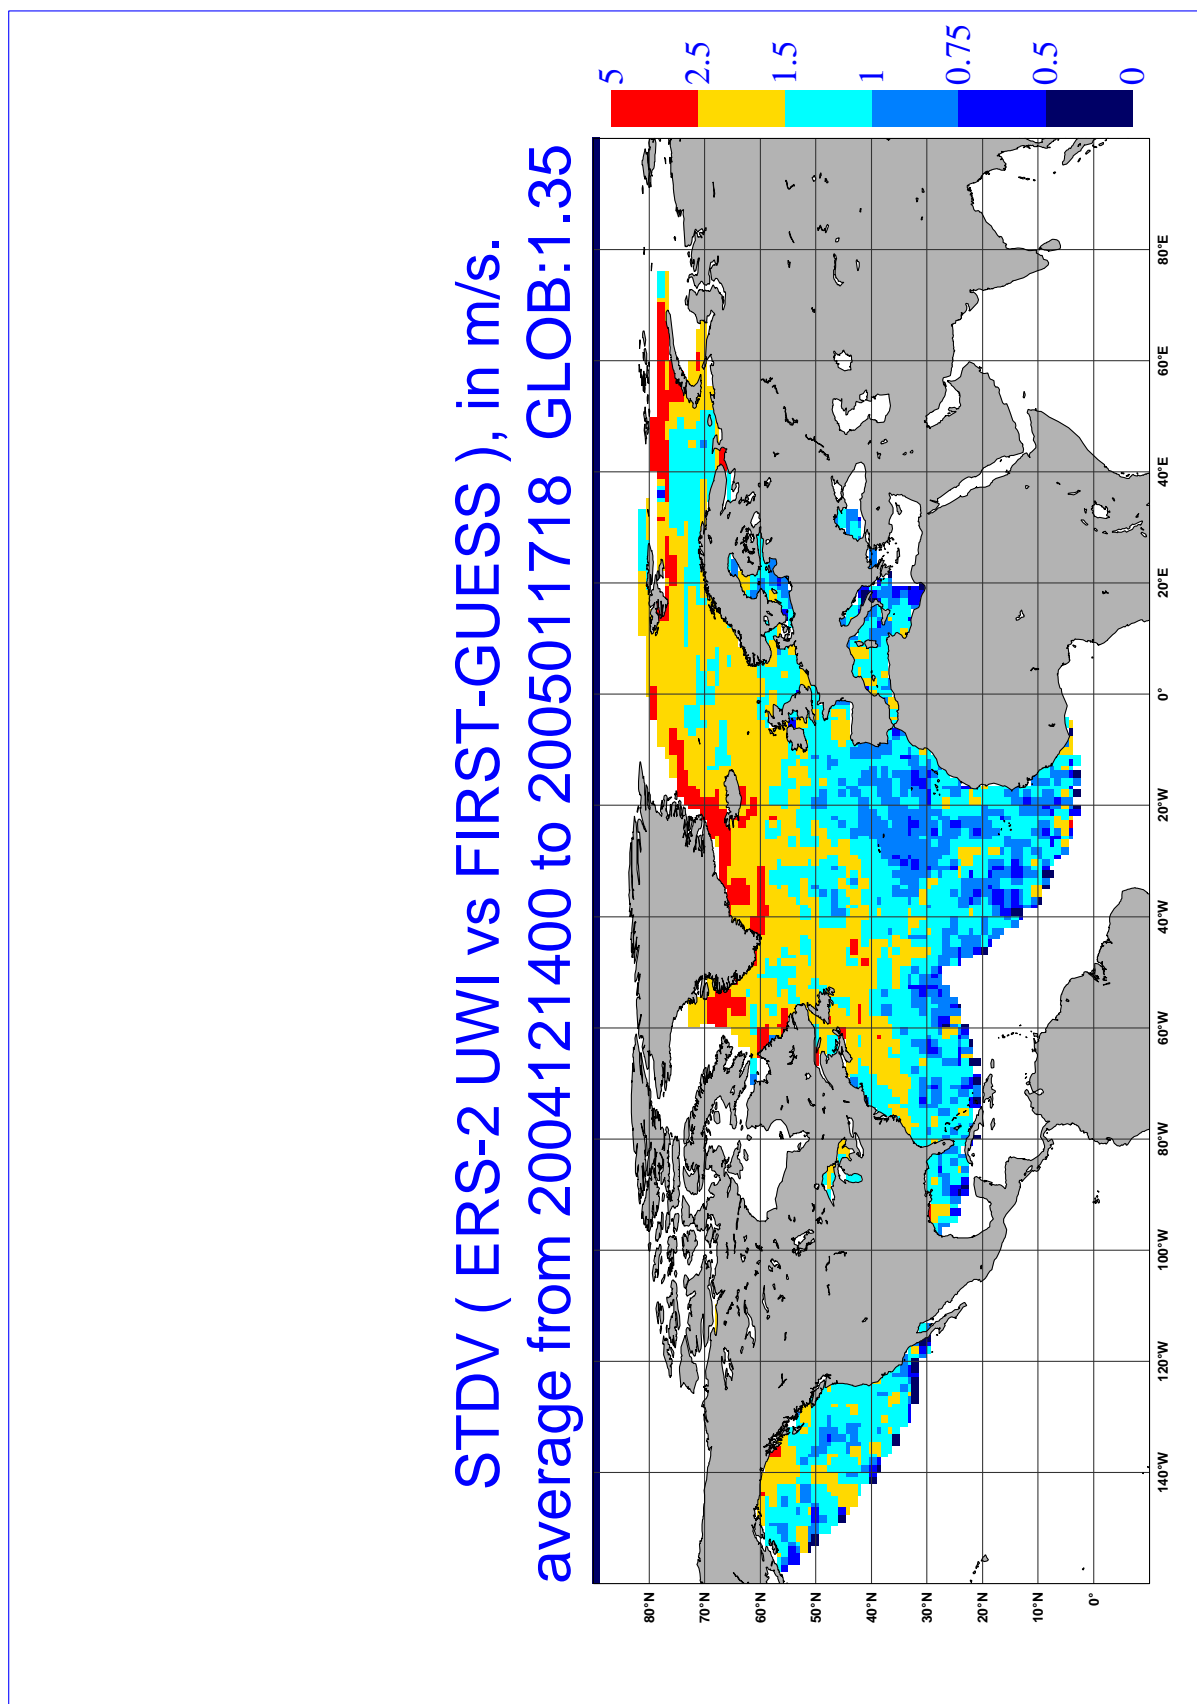

FIGURE 13 The same as Figure 12, but now for the relative bias (top panel) and standard deviation (lower panel) with ECMWF first-guess winds.

4.3.1 Distance to cone history

The distance to the cone history is shown in Figure 14. Curves are based on data that passed all QC, including the test on the Kp -yaw flag, however subject to the land and sea-ice check at ECMWF (see cyclic report 88 for details).

Like for cycle 100, time series are (due to lack of statistics) very noisy, especially for the first nodes. Most spikes were found to be the result of low data volumes. Note the large amount of rejections around the event discussed above. Compared to cycle 100, the average level was almost equal (from 1.18 to 1.19), and is now about 10 % higher than for nominal data (see top panel Figure 11).

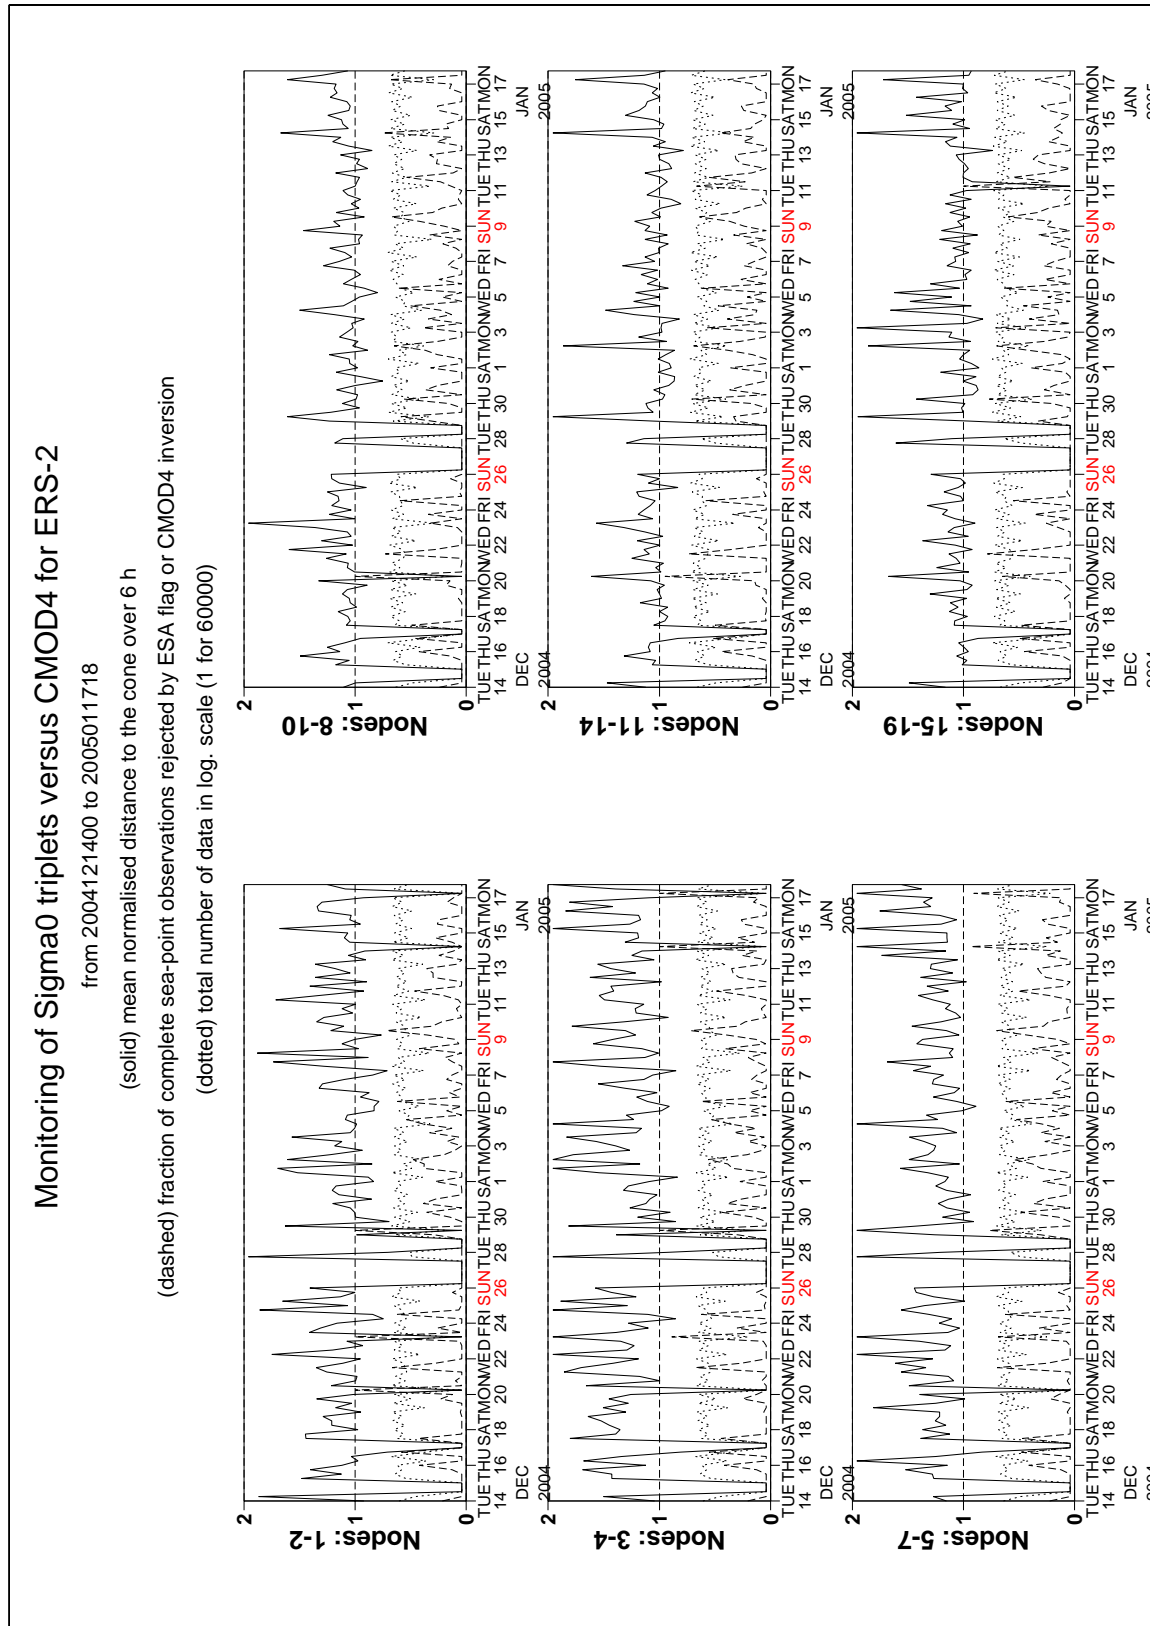

FIGURE 14 Mean normalised distance to the cone computed every 6 hours for nodes 1-2, 3-4, 5-7, 8-10, 11-14 and 15-19 (solid curve close to 1 when no instrumental problems are present). The dotted curve shows the number of incoming triplets in logarithmic scale (1 corresponds to 60,000 triplets) and the dashed one indicates the fraction of complete (based on the land and sea-ice mask at ECMWF) sea-located triplets rejected by ESA flags, or by the wind inversion algorithm (0: all data kept, 1: no data kept).

4.3.2 UWI minus First-Guess history

In Figure 15, the UWI minus ECMWF first-guess wind-speed history is plotted. The history plot shows several peaks, most of which are related to low data volumes. Similar results apply for the history of de-aliased CMOD4 winds versus FG (Figure 17).

Figure 19 displays the locations for which UWI winds were more than 8 m/s weaker (top panel) and more than 8 m/s stronger (lower panel) than FG winds. Like for cycle 100, the number of such collocations is low.

In Figure 20 two cases from the in Figure 19 shown collocations are illuminated.

The top panel displays a case for 17 January 2005 South-East of Greenland. It shows some differences in the details near the center of the low. The compared to ECMWF winds much weaker UWI winds (35 versus 60 knots) a few degrees to the south is for a large part due to the saturation behaviour of the CMOD4 geophysical model function.

The lower panel shows for 17 December 2004 a Mistral case West of Marseille, observed by ERS-2 but underestimated by the ECMWF first-guess field.

Average bias levels and standard deviations of UWI winds relative to FG winds are displayed in Table 6.

Table 6 Wind speed and direction biases

	Cycle 100		Cycle 101	
	UWI	CMOD4	UWI	CMOD4
Speed STDV	1.59	1.57	1.68	1.66
Node 1-2	1.70	1.65	1.85	1.79
Node 3-4	1.59	1.57	1.70	1.68
Node 5-7	1.51	1.50	1.62	1.61
Node 8-10	1.51	1.50	1.56	1.54
Node 11-14	1.54	1.53	1.61	1.60
Node 15-19	1.58	1.57	1.65	1.65
Speed BIAS	-0.65	-0.63	-0.80	-0.77
Node 1-2	-1.27	-1.22	-1.48	-1.42
Node 3-4	-0.96	-0.89	-1.13	-1.06
Node 5-7	-0.68	-0.63	-0.81	-0.77
Node 8-10	-0.49	-0.47	-0.60	-0.59
Node 11-14	-0.45	-0.45	-0.58	-0.57
Node 15-19	-0.44	-0.45	-0.57	-0.57
Direction STDV	44.6	19.4	27.9	18.1
Direction BIAS	-2.1	-3.4	-2.8	-3.2

From this it is seen that the bias of both the UWI and CMOD4 product have become more negative, in a rather homogeneous manner. The average bias level comparable to that for nominal data in 2000 (UWI: -0.80 m/s now, was -0.79 m/s for cycle 59).

The evolution of the bias from cycles 92 to 101 is displayed in the top panel of Figure 25. The red curve is the 5-day moving average for the at ECMWF inverted ERS-2 winds; i.e., CMOD5 since 9 March 2004. Blue vertical dashed lines indicate ECMWF model changes. This plot shows that the up-going line since end July 2004 has reached a constant level. For

QuikSCAT, the positive trend in the globally averaged bias of (at ECMWF inverted and bias-corrected) QuikSCAT winds (middle panel) did continue, however, showed a swift drop in January 2005.

The standard deviation of UWI winds compared to cycle 100 has become higher (1.68 m/s, was 1.59 m/s) in a rather uniform way. The seasonal trend makes an objective statement on quality evolution impossible.

For cycle 101 the (UWI - FG) direction standard deviations were ranging between 15 and 60 degrees (Figure 8). Sharp peaks are the result of low data volumes. The average performance for UWI wind direction has improved (STDV 27.9 degrees, was 44.6 degrees, bias -2.8 degrees, was -2.1 degrees), the difference being the result of an anomaly observed in the de-aliasing for cycle 100 (for details, see previous monitoring report).

4.3.3 Scatter plots

Scatter plots of FG winds versus ERS-2 winds are displayed in Figures 21 to 24. Values of standard deviations and biases are slightly different from those displayed in Table 6. Reason for this is that, for plotting purposes, the in 0.5 m/s resolution ERS-2 winds have been slightly perturbed (increases scatter with 0.02 m/s), and that zero wind-speed ERS-2 winds have been excluded (decreases scatter with about 0.05 m/s).

The scatter plot of UWI wind speed versus FG (Figure 21) is very similar to that for (at ECMWF inverted) de-aliased CMOD4 winds (Figure 23). It confirms that the ESACA inversion scheme is working properly. The enhanced standard deviation compared to cycle 100 (1.71 m/s, was 1.61 m/s), originates from a more intense wind climate.

Winds derived on the basis of CMOD5 are displayed in Figure 24.

The relative standard deviation is lower than for CMOD4 winds (1.62 m/s versus 1.70 m/s). Although compared to ECMWF FG, CMOD5 winds are -0.19 m/s slower. However a much larger negative bias is observed for strong winds.

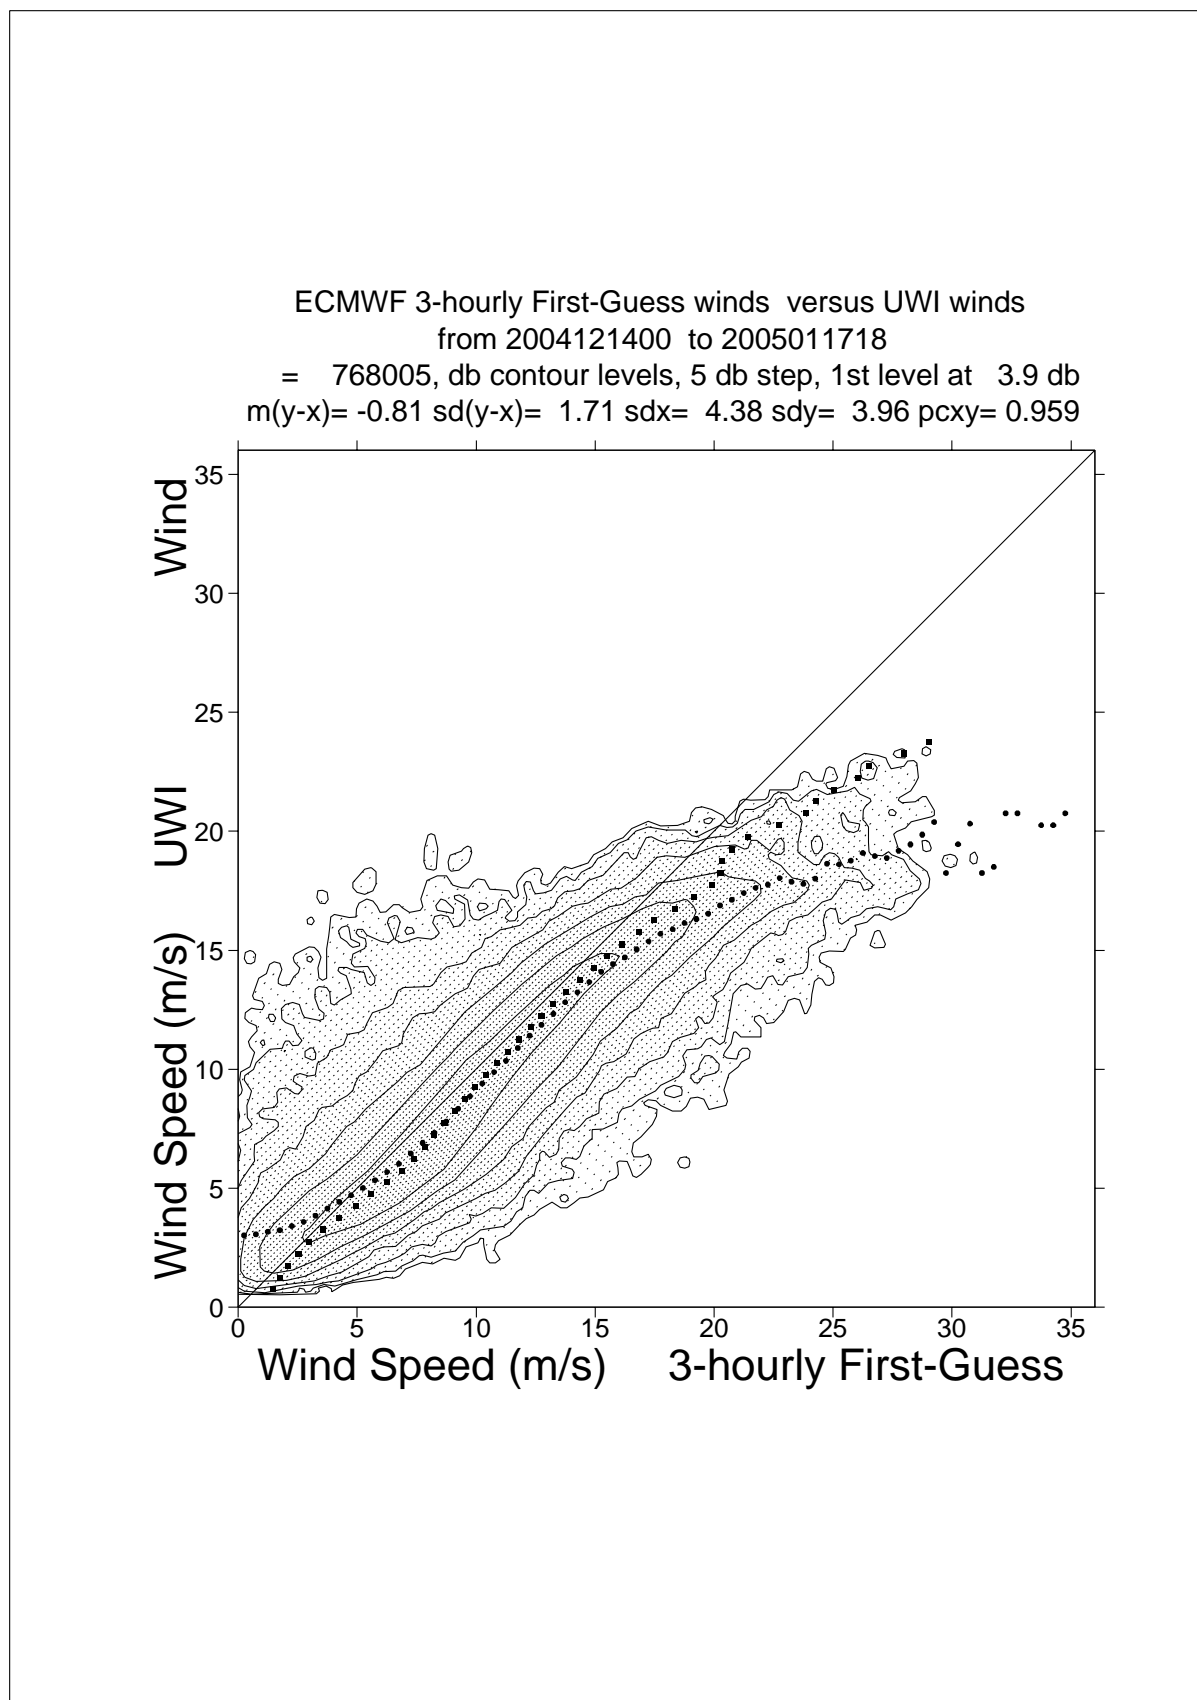

FIGURE 21 Two-dimensional histogram of first guess and UWI wind speeds, for the data kept by the UWI flags, and QC based on the ECMWF ice and land and sea-ice mask. Circles denote the mean values in the y-direction, and squares those in the x-direction.

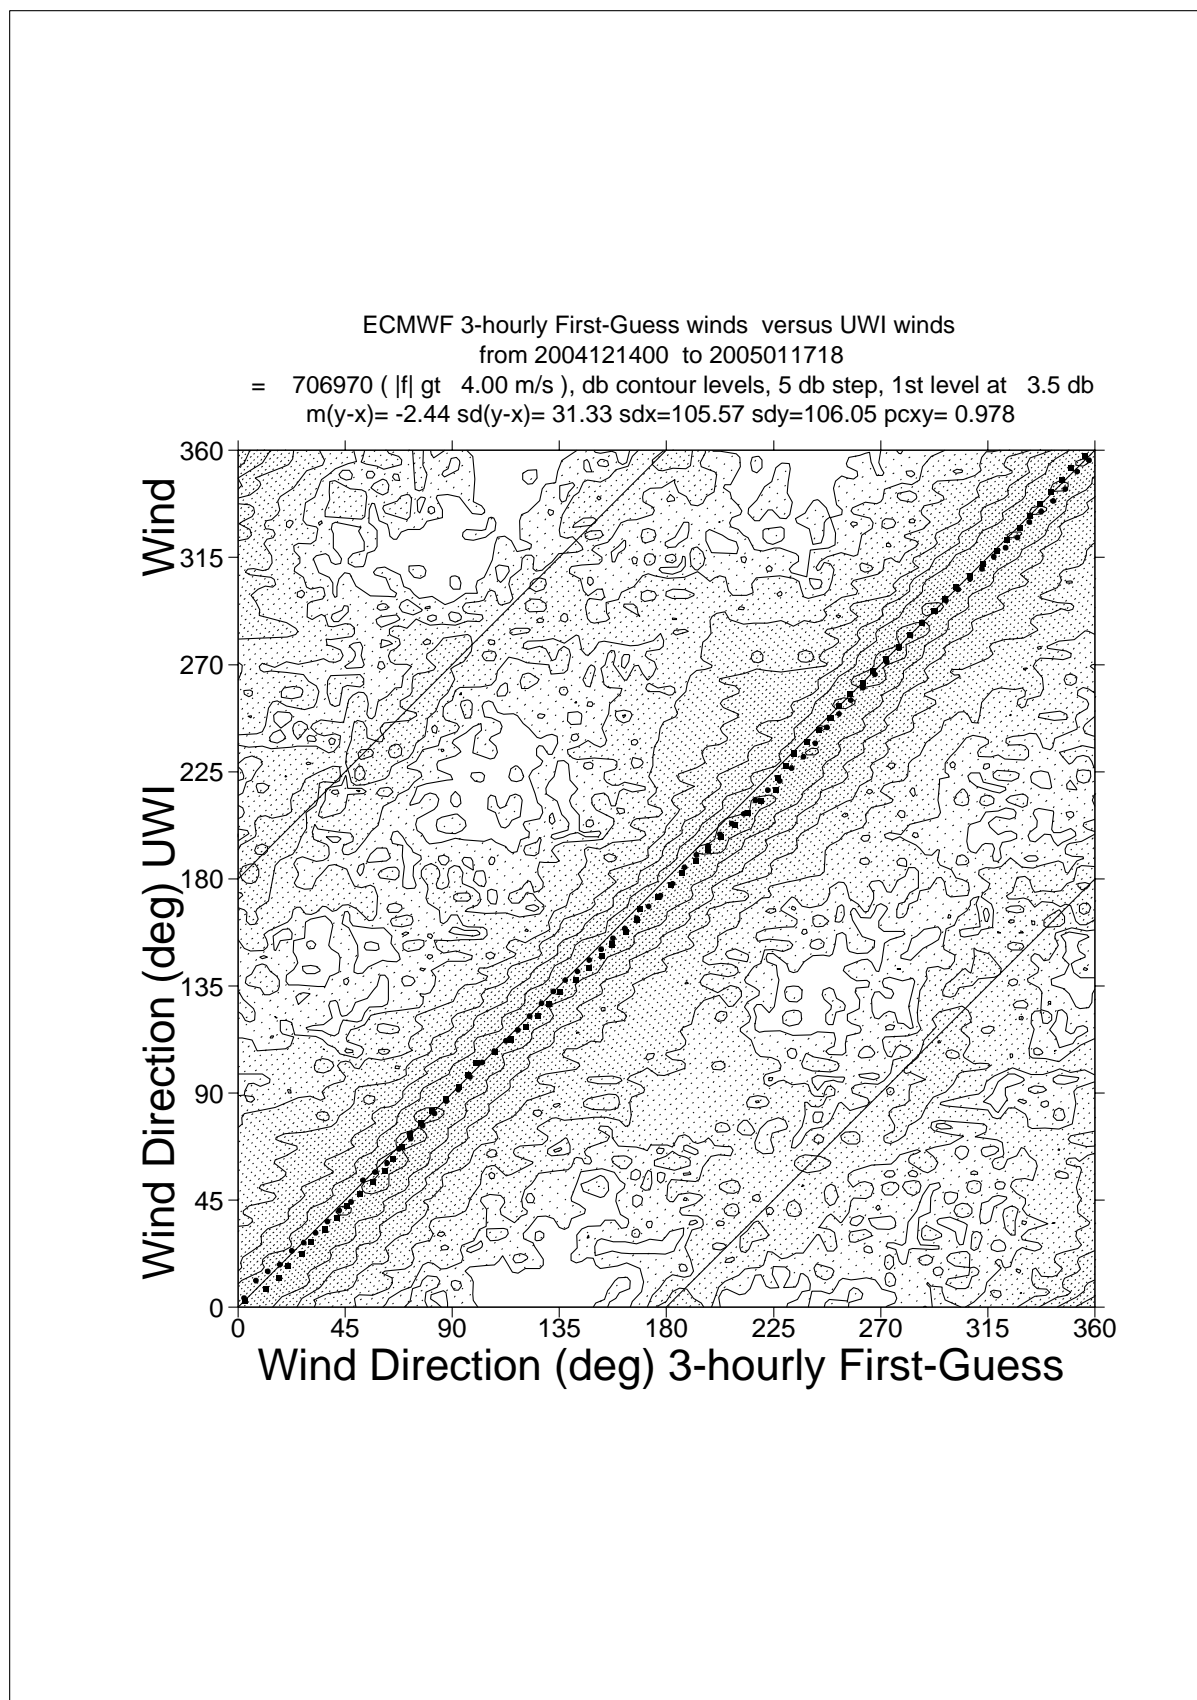

FIGURE 22 Same as Fig. 21, but for wind direction. Only wind speeds higher than 4m/s are taken into account.

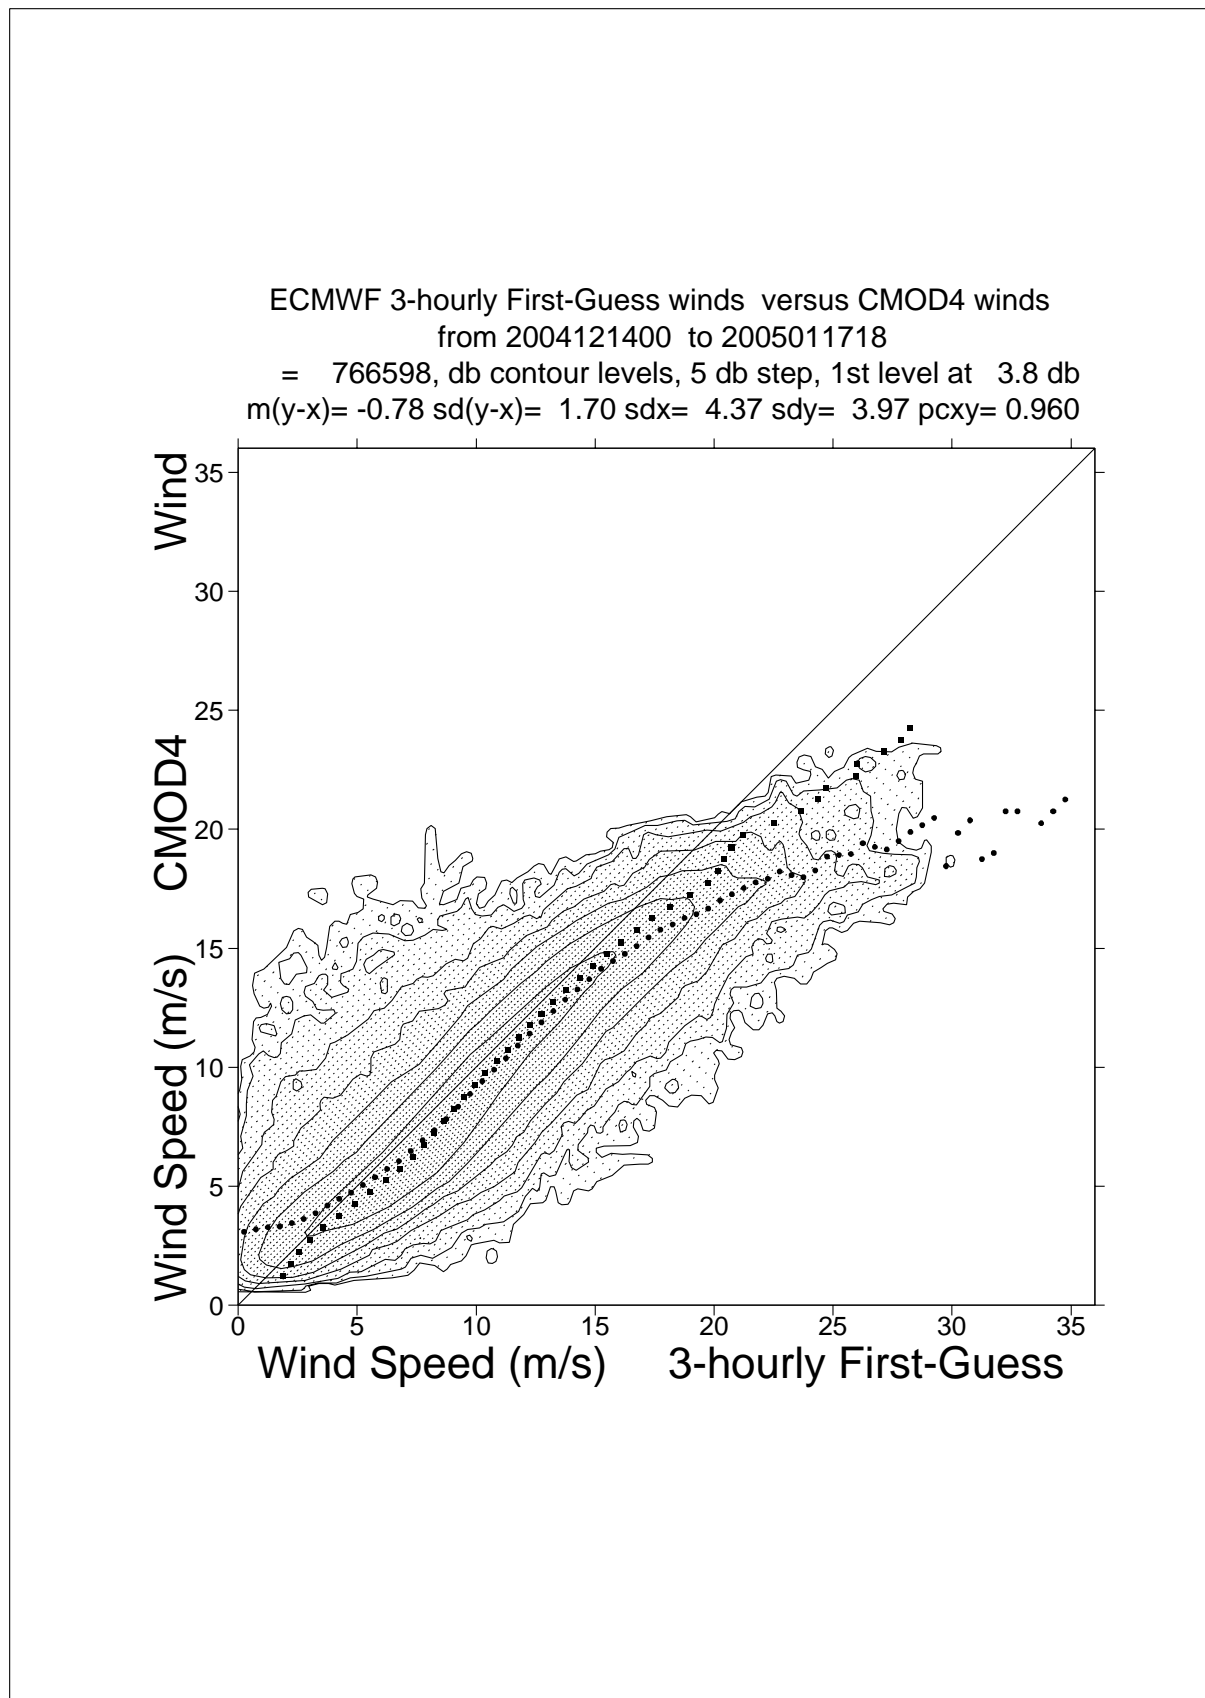

FIGURE 23 Same as Fig. 21, but for de-aliased CMOD4 winds.

FIGURE 24 Same as Fig. 21, but for de-aliased CMOD5 winds.

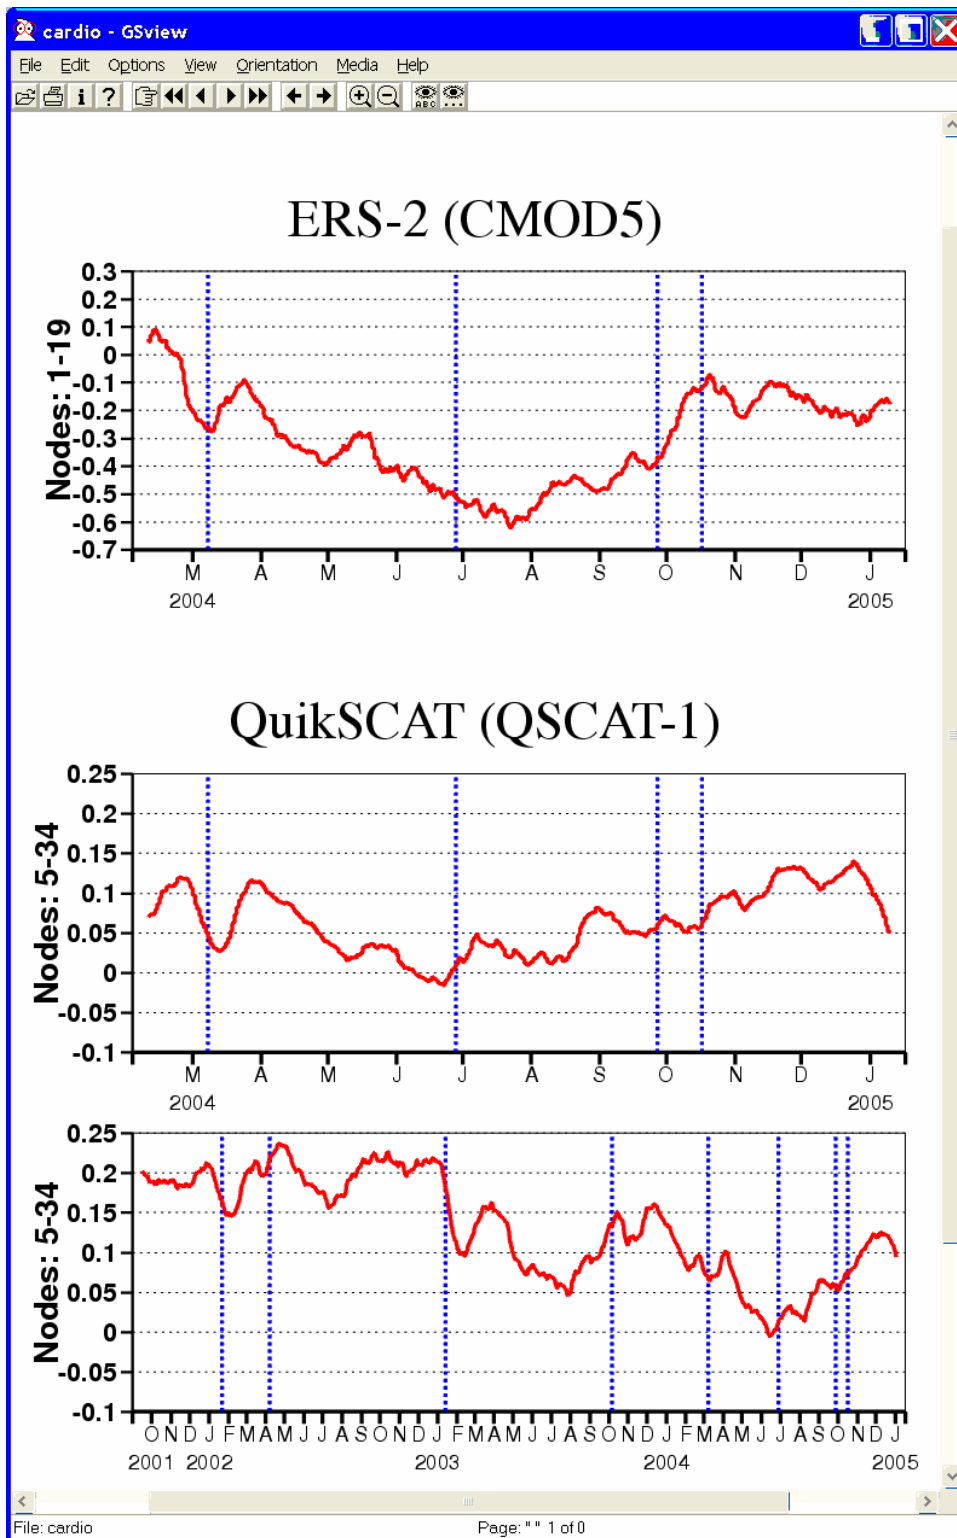

FIGURE 25 Bias relative to FG winds of the wind speed of ERS-2 winds (based on bias-corrected CMOD4 before 9 March 2004, and on CMOD5 afterwards) for nodes 1-19 (top panel) respectively of 50-km QuikSCAT (based on the QSCAT-1 model function) for nodes 5-34 (i.e., inner-beam zone; middle and lower panels) versus ECMWF first guess for the period of cycle 92 to 101. Curves represent centered 15-day running means for the top and middle panel, and a 30-day running mean for the lower panel. Vertical dashed blue lines mark ECMWF model changes

5 Yaw error angle estimation

The yaw error angle estimation is computed on-ground by the ESACA processors. The full set of results of the yaw processing is stored in an internal ESA product named HEY (Helpful ESA Yaw) disseminated from the ground station to ESRIN. The estimation of the yaw error angle is based on the Doppler shift measured on the received echo. That estimation can be done with a good accuracy only for small yaw error angle (in the range between +/-4 deg.). Above that range, due to high Doppler frequency shift the signal spectrum is outside the receiver bandwidth and the yaw estimation is strongly degraded. Details regarding the yaw processing can be found on the following document (chapter 9): <http://earth.esa.int/pcs/ers/scatt/articles/soamain-030521.pdf>.

The yaw error angle estimation aims to compute the correct acquisition geometry for the three Scatterometer antenna throughout the entire orbit. The Yaw error angle information is used in the radar equation to derive the calibrated backscattering (σ nought) from the Earth surface and to select the echo samples associated to one node. In ESACA the definition of the node position is as the one adopted in the old processor (for details see: http://earth.esa.int/pcs/ers/scatt/articles/scatt_work98_processing.pdf). In such way the distance between the nodes (both along and across track) is kept constant (25 Km) and what is changing in function of the yaw error angle is the number of echo samples that contributes to the node calculation and the incidence angle of the measurement. This because the three Scatterometer antennae could see the node with a different geometry due to an arbitrary variation of the yaw angle along track. The number of samples that actually contributes to a node and the yaw flag can be retrieved from the UWI Data Set Record (DSR) product. For that reason the definition of few fields in the UWI product has been updated. For details see the Scatterometer cyclic report - cycle 90 -. The Figure 26 (since beginning of HEY dissemination) and Figure 27 (cycle) show for each orbit the average Doppler frequency shift (first 3 plots Fore Mid and Aft antenna), the minimum, maximum and mean yaw (fourth plot), the yaw standard deviation (fifth plot) and the percentage of source packets acquired with a yaw error angle outside the range +/- 2 degrees (sixth plot).

On average the yaw evolution is within the specification for the ESACA processor to assure calibrated data. The evolving yaw bias occurred in June 2004 has been reported to the flight segment and corrective actions have been put in place to compensate for.

The result of the yaw monitoring for cycle 101 is a yaw error angle within the expected nominal range (+/- 2 degrees) with an average level around 0 deg. for most of the orbit. Since beginning of January 2005 an increase of the yaw angle error is noted (see also the increase of the number of pcd flag set). This is due to an enhanced solar activity which could have influenced the air drag and disturbing torques on the satellite.
