ERS-2 Wind Scatterometer Cyclic Report

From 22nd January 2007 to 26th February 2007
Cycle 123
Prepared by:	G. De Chiara	(scat@dpqc.org)
Approved by:	R. Crapolicchio	(scat@dpqc.org)
Inputs from:	H. Hersbach	(ECMWF)

Table of Content

1   <u>Introduction and Summary</u>

The document includes a summary of the daily quality control made within the DPQC (Data Processing Quality Control) and various sections describing the results of the investigations and studies of "open-problems" related to the Scatterometer. In each section results are shown from the beginning of the mission in order to see the evolution and to outline possible "seasonal" effects. An explanation for the major events which have impacted the performance since launch is given, and comments about the recent events which occurred during the last cycle are included. This report covers the period from 22nd January 2007 to 26 February (cycle 123) and includes the results of the monitoring activity performed by ESRIN and ECMWF.

This document is available on line at: http://earth.esa.int/pcs/ers/scatt/reports/pcs_cyclic/

Mission events

The following bullets summarize the major mission facts for cycle 123:

• The ERS-2 satellite was piloted in ZGM throughout the cycle.
• The ESACA processor worked nominally without faults.
• The following anomalies occurred during the reporting period:
   The AMI was in Standby/MCMD Refused mode from 11.14 to 14.25 on February 7th due to internal error.
   The AMI was in Heater and MCMD Refused modes from 03.10 to 07.40 on February 21st due to HPA arcing.
• A series of planned manoeuvre (FCM and OCM) was performed on February 1st, 13th and 14th.
   During the manoeuvre data accuracy could be degraded. The user can filter out that data set by checking the Doppler and yaw quality flag inside the UWI product or the combined Kp-Yaw flag for the BURF product.
• For the entire period of cycle 123, ERS-2 Scatterometer data was used in the 4D-Var data assimilation system at ECMWF.

News on the ERS mission is available on line: http://earth.esa.int/ers/new_ers_news.html

Data Coverage

After the on board tape recorder failure in July 2003, data is acquired in real time whenever

within the visibility range of a ground station. For cycle 123 data coverage stayed as for the previous cycle. The data coverage includes: the North-Atlantic, the Mediterranean, the Caribbean, the Gulf of Mexico, a small part of the Pacific west from the US Canada and Central America, the Chinese and Japanese Sea, a small part of the Indian Ocean South-east of Thailand and Indonesia, and the Southern Ocean south of Australia and New Zealand.

Yaw performance

The result of the yaw monitoring for cycle 123 is an average (per orbit) yaw error angle within the expected nominal range (+/- 2 degrees) centered on 0 deg. for most of the orbits.

Calibration performance

• Calibration data from Transponder are not available since January 2005. This is due to a hardware failure on the transponder. The repair of such device is still under evaluation. The calibration data acquired until 2005 in the ZGM will be re-processed with TOSCA (Tool for Scatterometer Calibration) and the results will be provided in this report when available.
• Due to the regional mission scenario the calibration performances over the Brazilian rain forest are not available because that area is not covered by the ESA ground station. The chance to install a new station to cover the calibration site is still under investigation as well as the possibility to use stable ice area in Greenland or Antarctic to monitor the instrument calibration.
• The Ocean Calibration monitoring is performed by ECMWF. The average backscatter bias level is similar to cycle 122 (-0.41 dB, unchanged) being around 0.05 dB less negative than for nominal data in 2000. The situation is similar to that of one year ago (see cyclic report 113). Therefore, the method of ocean calibration will probably only provide accurate information on calibration levels for globally averaged data, for which local seasonal effects are filtered out.

Instrument performance

• During the cycle 123 the mean transmitted power evolution had a mean decrease of 0.10 dB per cycle according to the nominal decreasing trend noted since the beginning of the mission. The transmitted power is continuous monitored and results on the trend will be reported in the next cyclic report.
• The evolution of the noise power during the cycle 123 was stable. The daily average for the

Fore and Aft beam noise is around 1.65 ADC (I) and around 1.5 ADC (Q) respectively. For the Mid beam the noise is not measurable.

• During the cycle 123 the Doppler compensation evolution was stable. The daily average of the CoG of the compensated received signal was around 26 Hz and -17 Hz for the Fore and Aft antenna respectively. For the Mid antenna it was around 200 Hz. The standard deviation of the CoG was around 1500 Hz for the Fore and Aft antenna and around 2700 Hz for the Mid antenna. These values are within the nominal range.

Product performance

During Cycle 123 data was received between 21:04 UTC 22 January 2007 and 20:58 UTC 26 February 2007. Received data was grouped into 6-hourly batches (centred around 00, 06, 12 and 18 UTC). No data was received for such batches between 18 UTC 23 January and 18 UTC 24 January 2007 (BUFR data was disseminated with delay to meteorological institutes due to problems in dissemination system), 06 UTC 25 January 2007 and 00 UTC 7 February 2007.

Compared to Cycle 122, the UWI wind speed relative to ECMWF first-guess (FG) fields showed a somewhat higher standard deviation (1.60 m/s, was 1.55 m/s). Bias levels were slightly less negative (-0.86 m/s, was -0.77 m/s).

The PCS geophysical monitoring reports a wind speed bias (UWI vs 18 or 24 hour forecast) of 0.6 m/s and a speed bias standard deviation around 1.9 m/s. The direction deviation performance is stable with more than 98% of the nodes with a wind direction in agreement with the ECMWF winds.

2   <u>Calibration Performances</u>

The calibration performances are estimated using three types of target: a man made target (the transponder) and two natural targets (the rain forest and the ocean). This approach allow us to design the correct calibration using a punctual but accurate information from transponders and an extended but noisy information from rain forest and ocean for which the main component of the variance comes from the geophysical evolution of the natural target and from the backscattering models used. These aspects are in the calibration performance monitoring philosophy. The major goals of the calibration monitoring activities are the achievement of a "flat" antenna pattern profile and the assurance of a stable absolute calibration level.

2.1   Gain Constant over transponder

One gain constant is computed per transponder per beam from the actual and simulated two-dimensional echo power, which is given as a function of the orbit time and range time. This parameter clearly indicates the difference between "real instrument" and the mathematic model. In order to acquire data over the transponder the Scatterometer must be set in an appropriate operational mode defined as "Calibration Mode". Since January 2001 with the operations in Zero Gyro Mode (ZGM) the satellite attitude is not stable as it was in the nominal Yaw Steering Mode (YSM). In particular there is a non-predictable variation of the yaw error angle along the orbit. For that reason the gain constant data computed by the CALPROC processor, that assumes a stable orbit, are meaningless and a new calibration processor is under development. In the mean time, data from the Transponder are still acquired and archived for future re-processing. The reprocessed gain constants will be provided in this section when available. For the gain constant computed during the nominal YSM please refer to the Scatterometer cyclic report cycle 60.

2.2   Ocean Calibration

The average sigma0 bias levels (compared to simulated sigma0's based on ECMWF model FG winds) stratified with respect to antenna beam, ascending or descending track and as function of incidence angle (i.e. across-node number) is displayed in Figure 1.

Inter-node and inter-beam dependencies are smaller compared to Cycle 122, as well as average levels (-0.41 dB, unchanged), being around 0.05 dB less negative than for nominal data in 2000 (see Figure 1 of the reports for Cycle 48 to 59). The situation is similar to that of one year ago (see cyclic report 113). Therefore, the method of ocean calibration will probably

only provide accurate information on calibration levels for globally or yearly averaged data sets.

The data volume of descending tracks was lower (by 12%) than for ascending tracks. This is due to an intensive SAR acquisition campaign during the descending passes (See the AMI instrument mode in Figure 8).

FIGURE 1 ERS-2   Scatterometer   Ocean   Calibration   cycle   123.   Ratio   of <sigma_0^0.625>/<CMOD4(First Guess)^0.625> converted in dB for the fore beam (solid line), mid beam (dashed line) an aft beam (dotted line), as a function of incidence angle for descending and ascending tracks. The thin lines indicate the error bars on the estimated mean. First-guess winds are based on the in time closest (+3h, +6h, +9h, or +12h) T511 forecast field, and are bilinearly interpolated in space.

2.3   Gamma-nought over the Brazilian rain forest

Although the transponders give accurate measurements of the antenna attenuation at particular points of the antenna pattern, they are not adequate for fine tuning across all incidence angles, as there are simply not enough samples. The tropical rain forest in South America has been used as a reference distributed target. The target at the working frequency (C-band) of ERS-2 Scatterometer acts as a very rough surface, and the transmitted signal is equally scattered in all directions (the target is assumed to follow the isotropic approximation). Consequently, for the angle of incidence used by ERS-2 Scatterometer, the normalized backscattering coefficient (sigma nought) will depend solely on the surface effectively seen by the instrument:

$$S^0 = S \bullet \cos\theta$$

With this hypothesis it is possible to define the following formula:

$$\gamma^0 = \frac{\sigma^0}{\cos\theta}$$

Using the above equation, the gamma nought backscattering coefficient over the rain forest is independent of the incident angle, allowing the measurements from each of the three beams to be compared. The test area used by the PCS is located between 2.5 degrees North and 5.0 degrees south in latitude and 60.5 degrees West and 70.0 degrees West in longitude. That area is actually not covered by the Regional mission scenario (since cycle 86 onwards) and therefore the calibration monitoring activity over the Brazilian rain forest is suspended because no data are available. The chance to continue the monitoring activity with a new receiving station covering the Brazilian rain forest is under investigation. The following paragraphs will report on the results when data will be available.

2.4   Antenna pattern: Gamma-nought as a function of elevation angle

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason the antenna patterns in function of the elevation angle have not been computed.

2.5   Antenna pattern: Gamma-nought as a function of incidence angle

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason the antenna patterns in function of the incidence angle have not been computed.

2.6   Gamma nought histograms and peak position evolution

As the gamma nought is independent from the incidence angle, the histogram of gamma

nought over the rain forest is characterized by a sharp peak. The time-series of the peak position gives some information on the stability of the calibration. This parameter is computed by fitting the histogram with a normal distribution added to a second order polynomial:

$$F(x) = A_0 \cdot \exp\left(-\frac{z^2}{2}\right) + A_3 + A_4 \cdot x + A_5 \cdot x^2$$

where: $z = \dfrac{x - A_1}{A_2}$

The parameters are computed using a non linear least square method called "gradient expansion". The position of the peak is given by the maximum of the function F(x). The histograms are computed weekly (from Monday to Sunday) for each antenna individually "Fore", "Mid" and "Aft" and for ascending and descending passes with a bin size of 0.02 dB. Due to the regional mission scenario data over the Brazilian rain forest are not available and the histograms have not been computed. For the time series since the beginning of the mission please refer to the Scatterometer cyclic report cycle 86.

2.7   Gamma nought image of the reference area

Due to the regional mission scenario data over the Brazilian rain forest are not available and the histograms have not been computed.

2.8   Sigma nought evolution

Due to the regional mission scenario data over the Brazilian rain forest are not available. For that reason none update has been done to the sigma nought evolution time series. For the time series since the beginning of the mission until June 2003 please refer to the Scatterometer cyclic report cycle 86.

2.9   Antenna temperature evolution over the Rain Forest

Due to the regional mission scenario data over the Brazilian rain forest are not available. For the time series since the beginning of the mission please refer to the Scatterometer cyclic report cycle 86.

3 Instrument performance

The instrument status is checked by monitoring the following parameters:

• Centre of Gravity (CoG) and standard deviation of the received signal spectrum after the on-ground Doppler Compensation filter. This parameter is useful for the monitoring of the orbit stability, the performances of the Doppler compensation filter, the behavior of the yaw steering mode and the performances of the devices in charge for the satellite attitude (e.g. gyroscopes, Earth sensor, Sun sensor).

• Noise power I and Q channel.

• Internal calibration pulse power.

The latter is an important parameter to monitor the transmitter and receiver chain, the evolution of pulse generator, the High Power Amplifier (HPA), the Traveling Wave Tube (TWT) and the receiver. These parameters are extracted daily from the UWI products and averaged. The evolution of each parameter is characterized by a least square line fit. The coefficients of the line fit are printed in each plot.

3.1 Centre of gravity and standard deviation of received power spectrum

The Figure 2 shows the evolution of the two parameters for each beam since the beginning of the ERS-2 mission and Figure 3 shows the same evolution only for the cycle 123.

The tendency during the nominal Yaw Steering Mode (YSM) period (beginning of the mission since the operation with the Mono Gyro (MGM) Attitude On-board Control System (AOCS) configuration on 7th February 2000) is a small and regular increase of the Centre of gravity (CoG) of received spectrum for the three antennae. During the YSM, two small changes can be detected in the CoG evolution. The first change is from 24th, January 1996 to 14th, March 1996, the second one is from 14th February 1997 to 22nd April 1997. The reason was a change in the pointing subsystem (DES reconfiguration) side B instead of side A after a depointing anomaly (see table 1 for the list of the all AOCS depointing anomaly occurred during the ERS-2 mission). During these periods side B was switched on. It is important to note that during the first time a clear difference in the CoG of the received spectrum is present only for the Fore antenna (an increase of roughly 100 Hz) while during the second time the change has affected all the three antennae (roughly an increase of 200 Hz, 50 Hz and

50 Hz for the fore, mid and aft antenna respectively).

At the beginning of 2000 the nominal 3-gyroes AOCS configuration (plus one Digital Earth Sensor -DES, and one Digital Sun Sensor -DSS and backups) was no more considered safe because 3 of the six gyros on-board were out of order or very noisy. For that reason the MGM was implemented as default piloting mode. The MGM configuration was designed to pilot the ERS-2 using only one gyro plus the DES and the DSS modules. Scope of ZGM configuration was to extend the satellite lifetime by using the available gyros one at the time.

With the MGM, an increase of roughly 200 Hz was observed at the end of the qualification period. After the AOCS commissioning phase this parameter further evolved within the nominal range with a negligible impact on the data quality.

In MGM configuration, the gyro 5 was used until 7th October 2000 when it failed. From 10th October 2000 to 24th October 2000 the gyro 6 was used. This explains the decrease of roughly 100Hz in the CoG of the received spectrum. From 25th October 2000 to 17th January 2001 the gyro 1 was used to pilot the ERS-2 satellite. On 17th January 2001 the AOCS was upgraded. The new configuration allows piloting the satellite without gyroscopes. Unfortunately a failure of the Digital Earth Sensor (DES A-side) caused ERS-2 to enter in Safe-Mode on the same day. On 25th January 2001 gyro #1 also failed.

Satellite attitude was recovered on 5th February 2001 with a coarse attitude control mode (EBM). During the period of safe mode the spacecraft had drifted out of the nominal dead band by some 30 Km. The nominal orbit was reached on 6th February 2001.
The EBM mode had a strong negative impact on the Scatterometer data quality and the dissemination of data products to end users was discontinued.

After that a series of AOCS upgrades has been implemented in order to improve the satellite attitude: on 30th March 2001 the Yaw steering law was re-introduced into the piloting function and on 7th June 2001 the Zero Gyro Mode (ZGM) has been implemented as nominal piloting mode. In ZGM the satellite attitude had an improvement in particular for the pitch and yaw error angle. This explains the reduction of the fluctuation in the received signal.

The CoG returns within its nominal value in February 2003 when the new ERS Scatterometer ground processor (ESACA) was put in operation (only for validation purposes) in Kiruna station. ESACA is able to compensate for errors in satellite attitude and to produce calibrated sigma noughts.

The evolution of the standard deviation of the CoG of the received spectrum was stable during the YSM phase. Small peaks are related with the events listed in Table 2. In MGM the evolution was within the nominal range while for the initial phase of the ZGM the performance was strong degraded. This because the on-ground Doppler filters was not able to compensate for the satellite degraded attitude. The introduction of the ESACA processor in February 2003 cured the problem.

On 8th December 2006 10:43 p.m. to 9th December 2006 07:18 anomaly in the on board Doppler Compensation occurred. That did not impact on the evolution of the CoG because the ESACA ground processor has compensated the receiver signal for the Doppler frequency shift. The Scat Team has carried out a deep analysis of the anomaly (see the technical note OSME-DPQC-SEDA-TN-06-0328 for further details).

TABLE 1 ERS-2 Scatterometer AOCS depointing anomaly list

Start of the anomaly			End of the anomaly			Remarks
24th January	1996	9:10 a.m.	26th January	1996	6:53 p.m.	AOCS depointing anomaly
14th February	1997	1:25 a.m.	15th February	1997	3:44 p.m.	AOCS depointing anomaly
3rd June	1998	2:43 p.m.	6th June	1998	12:47 a.m.	AOCS depointing anomaly
1st September	1999	8:50 a.m.	2nd September	1999	1:28 a.m.	
7th October	2000	4:38 p.m.	10th October	2000	4:49 p.m	depointing anomaly gyro 5 failure
24th October	2000	4:05 p.m.	25th October	2000	12:05 p.m.	depointing anomaly gyro 6 failure
17th January	2001		5th February	2001		gyro 1 failure Satellite in safe mode

TABLE 2 ERS-2 Scatterometer anomalies in the Doppler Compensation monitoring

Date start	Year	Date stop	Year	Reason
26th September	1996	27th September	1996	Missing on-board Doppler coefficient (after cal. DC converter test period)
6th June	1998	7th June	1998	No Yaw Steering Mode (after depointing anomaly)
2nd December	1998	3rd December	1998	Missing on-board Doppler coefficients (after AMI anomaly number 228)

16th February	2000	17th February	2000	Fine Pointing Mode (FPM) (due to AOCS mono-gyro qualification period)
14th April	2000	14th April	2000	Fine Pointing Mode (FPM)
5th July	2000	5th July	2000	Fine Pointing Mode (FPM) after instrument switch-on
27th September	2000	27th September	2000	Fine Pointing Mode (FPM) to upload AOCS software patch
2nd November	2000	2nd November	2000	Fine Pointing Mode (FPM)
5th December	2000	6th December	2000	Fine Pointing Mode (FPM) due to orbital manoeuvre
6th February	2001	30th March	2001	Extra Backup Mode (EBM) coarse attitude control
30th March	2001	17th June	2001	ZGM-EBM coarse attitude control
17th June	2001	21st August	2003	ZGM phase. Error in yaw angle not corrected in the ground segment processor. Data shall be reprocessed with ESACA.
24th March	2004	24th March	2004	Fine Pointing Mode (FPM) due to orbital manoeuvre
25th October	2004	27th October	2004	Series of orbital manoeuvres (OCM and FPM)
10th November	2004	11th November	2004	Intense geomagnetic storm
8th March	2005	8th March	2005	orbital manoeuvre (OCM)
11th March	2005	11th March	2005	orbital manoeuvre (FPM)
2nd November	2005	2nd November	2005	orbital manoeuvre (OCM)
1st March	2006	1st March	2006	orbital manoeuvre (OCM)
3rd November	2006	3rd November	2006	orbital manoeuvre (OCM) at 10:07:46
4th November	2006	4th November	2006	orbital manoeuvre (FCM) at 02:56:53 and 04:37:38
8th December	2006	9th December	2006	Missing on-board Doppler coefficients after AMI anomaly from 10:43 p.m. to 9th December 2006 07:18 a.m.
19th December	2006	19th December	2006	orbital manoeuvre (FCM) at 23:06:12
1st February	2007	1st February	2007	orbital manoeuvre (FCM) at 02:53:31
13th February	2007	13th February	2007	orbital manoeuvre (FCM) at 05:00:15 and 06:40:51 to anticipate the eastward drift expected from an OCM on the nextd day
14th February	2007	14th February	2007	orbital manoeuvre (OCM) at 09:30:29 for inclination correction
14th February	2007	14th February	2007	In orbit maintenance of gyros 3/4/6 while in Fine Pointing Mode
16th February	2007	16th February	2007	2-burn orbital manoeuvre (FCM) to correct the resulting in-plane component.

The Doppler compensation evolution for cycle 123 is showed in Figure 3. The monitoring shows a daily average of the CoG of the compensated received signal around 26 Hz and -17 Hz for the Fore and Aft antenna respectively. For the Mid antenna it was around 200 Hz. The standard deviation of the CoG was around 1500 Hz for the Fore and Aft antenna and around 2700 Hz for the Mid antenna. Those values are within the nominal range apart from 13rd and

14th February when a slight deviation can be noted in the daily statistics due to the orbital manoeuvre.
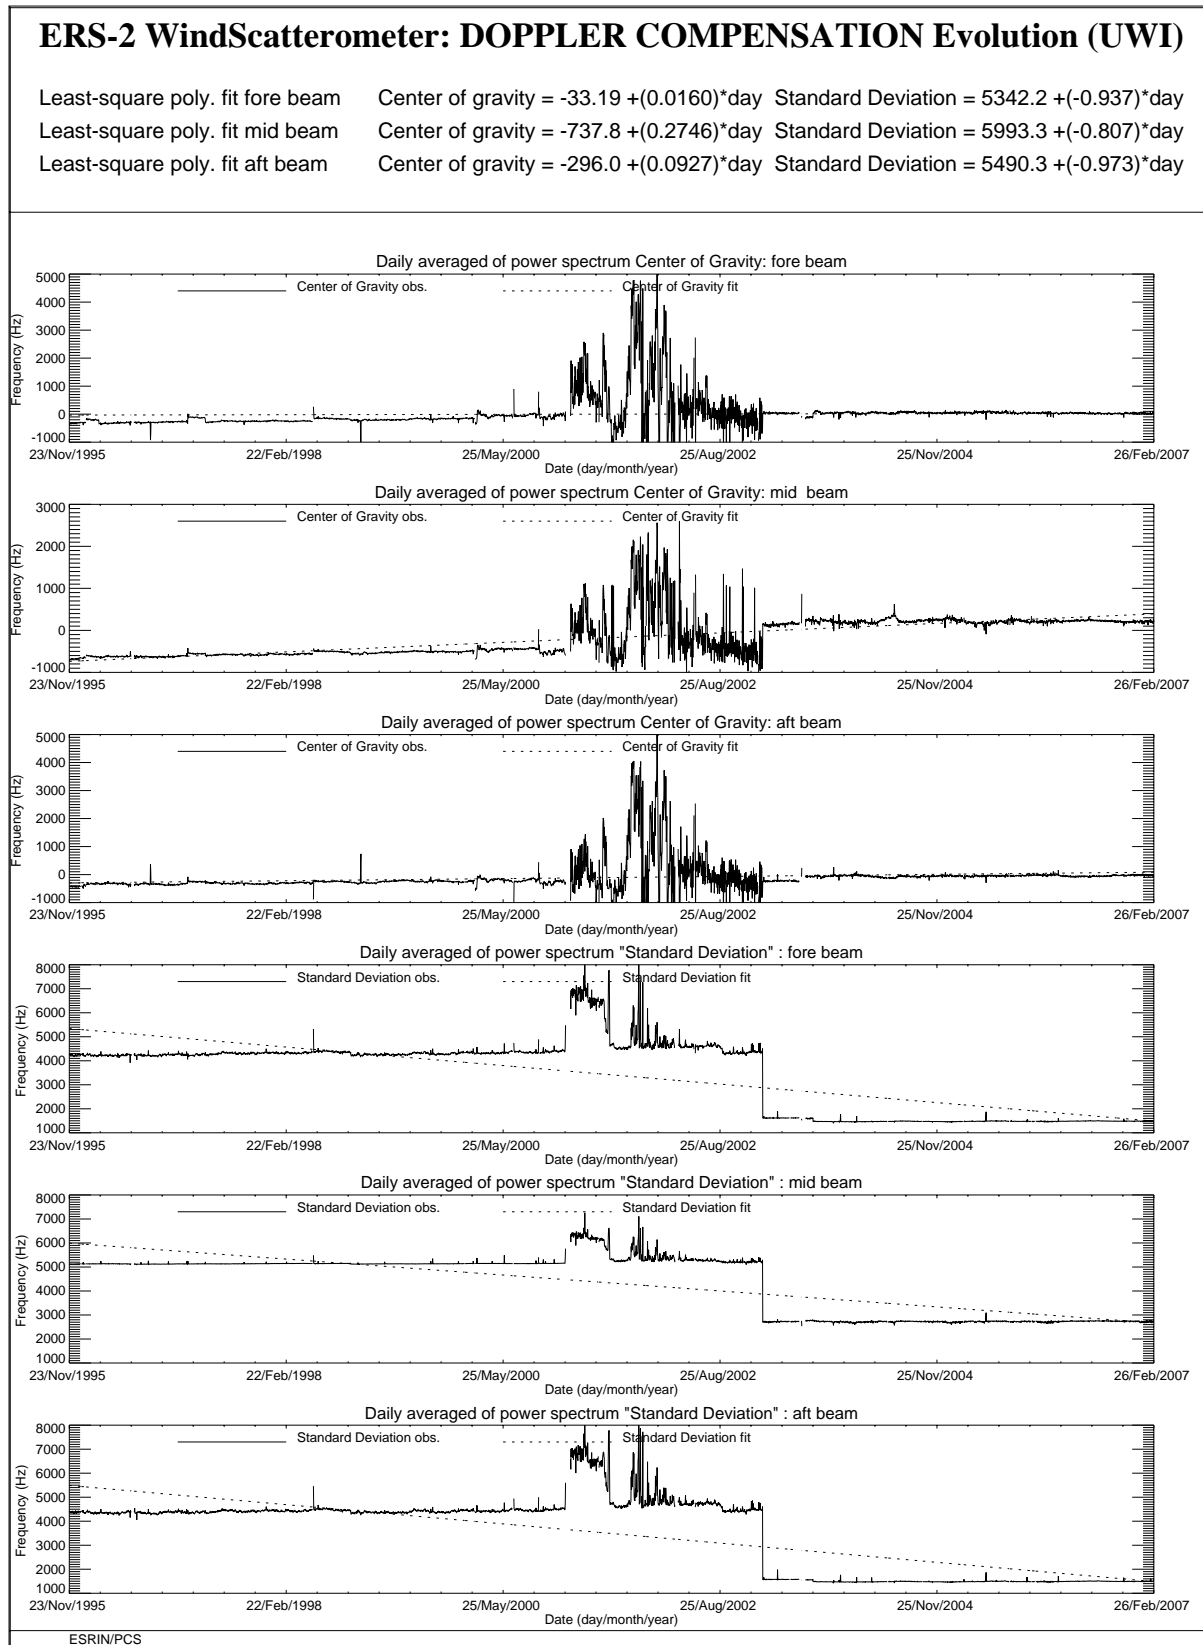

ERS-2 WindScatterometer: DOPPLER COMPENSATION Evolution (UWI)

Least-square poly. fit fore beam	Center of gravity = -33.19 +(0.0160)*day	Standard Deviation = 5342.2 +(-0.937)*day
Least-square poly. fit mid beam	Center of gravity = -737.8 +(0.2746)*day	Standard Deviation = 5993.3 +(-0.807)*day
Least-square poly. fit aft beam	Center of gravity = -296.0 +(0.0927)*day	Standard Deviation = 5490.3 +(-0.973)*day

3.2   Noise power level I and Q channel

The results of the monitoring are shown in Figure 4 (long-term) and Figure 5 (cycle 123). The first set of three plots presents the noise power evolution for the I channel while the second set shows the Q channel. From the plots one can see that the noise level is more stable in the I channel than in the Q one. The I and Q receivers are inside the same box and any external interference should affect both channel. The fact that the receivers are closer to the ATSR-GOME electronics could have some impact but there is no clear explanation on that behavior. From 5th December 1997 until November 1998 some high peaks appear in the plots. These high values for the daily mean are due to the presence for these special days of a single UWI product with an unrealistic value in the noise power field of its Specific Product Header. The analysis of the raw data used to generate these products lead in all cases to the presence of one source packet with a corrupted value in the noise field stored into the source packet Secondary Header. The reason why noise field corruption is beginning from 5th December 1997 and last until November 1998 is at present unknown. It is interesting to note that at the beginning of December 1997, we started to get as well the corruption of the Satellite Binary Times (SBTs) stored in the EWIC product. The impact in the fast delivery products was the production of blank products starting from the corrupted EWIC until the end of the scheduled stop time. A change in the ground station processing in March 1998 overcame this problem.

Since 9th August 1998 until March 2000 some periods with a clear small instability in the noise power have been recognized, Table 3 gives the detailed list.

TABLE 3 ERS-2 Periods with instability in the noise power

Start date	Stop date	Year
9th August	26th October	1998
29th November	6th December	1998
23rd December	24th December	1998
7th June	10th June	1999
17th August	22nd August	1999
8th September	9th September	1999
3rd October	8th October	1999
16th October	18th October	1999
26th October	28th October	1999
25th December	2nd January	2000
10th February	11th February	2000
19th March	26th March	2000

To better understand the instability of the noise power the PCS has carried out investigations in the Scatterometer raw data (EWIC) to compute the noise power with more resolution. The result is that for the orbits affected by the instability the noise power had a decrease of roughly 0.7 dB for the fore and aft signals and a decrease of roughly 0.6 dB in the mid beam case (see the report for the cycle 42). The decrease of the noise power during the orbits affected by the instability is comparable with the decrease of the internal calibration level that occurred during the same orbits. The reason of this instability (linked to the AMI anomalies) is still unknown. On 28th February 2003 the Scatterometer receiver gain has been increased by 3 dB to optimize the usage of the on-board ADC converter. This explains the increase of the noise for the Fore and Aft beam channel. For the mid beam channel the noise still remains not measurable.

On 17th February 2006 a high peak was detected in the noise power, causing the daily average for that day very high. The case has been deeply investigated and a technical note (Ref OSME-DPQC-SEDA-TN-06-0163) is available. The cause was an acquisition problem that corrupted one source packet and not an instrument anomaly. The same happened on April 24th 2006 (cycle 115).

On 8th September 2006 a high peak in the noise power of the Mid beam has been detected. The event occurred between 17:41:54 and 17:42:43 (UTC) and the noise power reached the value of 43 ADC (fore beam) and 19 ADC (mid beam). Those values had affected the daily average and are clear present in the plots of the Figure 4. That anomaly has been deeply investigated in the Technical Note OSME-DPQC-SEDA-TN-06-0251 and cannot be linked to any anomaly in the acquired data. The conclusion of the investigation was that a problem had occurred in the transmitter or in the pulse generator of the AMI instrument. At that time the AMI was in wind only mode so no additional comparison with SAR data can be done. Similar peaks had been noted also for September 15th and 18th. ESOC has checked the Mission Plan and noticed that in all three events the peak in the noise power occurred very close to 6 minutes after the start of a Wind mode and 40 minutes after ascending node crossing.

The evolution of the noise power during the cycle 123 was stable (see Figure 5). The daily average for the Fore and Aft beam noise is around 1.65 ADC (I) and around 1.5 ADC (Q) respectively. For the Mid beam the noise is not measurable.

ERS-2 WindScatterometer: NOISE Level Evolution (UWI)

Least-square line fit fore beam: I = 731.29 +(0.2499)*day   Q = 681.75 +(0.2363)*day

I channel: No line fit standard deviation too hight   Q channel: No line fit standard deviation too hight

Least-square line fit aft beam: I = 730.54 +(0.2399)*day   Q channel: No line fit standard deviation too hight

FIGURE 5 ERS-2 Scatterometer: noise power I and Q channel for cycle 123.

3.3   Power level of internal calibration pulse

For the internal calibration level, the results are shown in Figure 6 (long-term) and Figure 7 (cycle 123). The high value of the variance in the fore beam until August, 12th 1996 is due to the ground processing. In fact all the blank source packets ingested by the processor were recognized as Fore beam source packets with a default value for the internal calibration level. The default value was applicable for ERS-1 and therefore was not appropriate for ERS-2 data processing. On August 12th, 1996 a change in the ground processing LUT overcame the problem. Since the beginning of the mission a power decrease is detected. The power decrease is regular and affects the AMI when it is working in wind-only mode, wind/wave mode and image mode indifferently. The average power decrease is around 0.08 dB per cycle (0.0022 dB/day) and is clearer after August, 6th 1996 when the calibration subsystem has been changed. The reason of the power decrease is because the TWT is not working in saturation, so that a variation in the input signal is visible in the output. The variability of the input signal can be two-fold: the evolution of the pulse generator or the tendency of the switches between the pulse generator and the TWT to reset themselves into a nominal position. These switches were set into an intermediate position in order to put into operation the Scatterometer instrument (on 16th November 1995). To compensate for this decrease, on 26th October 1998 (cycle 37) 2.0 dB were added to the Scatterometer transmitted power and on 4th September 2002 (cycle 77) were added 3.0 dB. On 28th February 2003 (cycle 82) the Scatterometer receiver gain was increased by 3 dB to improve the usage of the on-board ADC converter. These events are clearly displayed by the large steps show in Figure 6.

Since 9th August 1998 until March 2000 the internal calibration level shows instability after an AMI or platform anomaly (see reports from cycle 35 to cycle 52). This instability is very well correlated with the fluctuations observed in the noise power. On 13th July 2000 a high peak (+3.5 dB) was detected in the transmitted power. This event has been investigated deeply by PCS and ESOC. The results of the analysis are reported in the technical note "ERS-2 Scatterometer: high peak in the calibration level" available in the PCS. The high transmitted power was detected after an arcing event which occurred inside the HPA. After that event the transmitted power had an average increase of roughly 0.14 dB.

During the cycle 123 the mean transmitted power evolution had a mean decrease of 0.10 dB per cycle according to the nominal decreasing trend. The transmitted power is continuous monitored and results confirming that trend or not will be reported in the next cyclic report.

4   Products performance

The PCS carries out a quality control of the winds generated from the WSCATT data. External contributions to this quality control (from ECMWF) are also reported in this chapter.

4.1   Products availability

One of the most important points in the monitoring of the products performance is their availability. The Scatterometer is a part of ERS payload and it is combined with a Synthetic Aperture Radar (SAR) into a single Active Microwave Instrument (AMI). The SAR users requirements and the constraints imposed by the on-board hardware (e.g. amount of data that can be recorded in the on-board tape) set rules in the mission operation plan.

The principal rules that affected the Scatterometer instrument data coverage are:
• Over the Ocean the AMI is in wind/wave mode (Scatterometer with small SAR imagettes acquired every 30 sec.) and the ATSR-2 is in low rate data mode.
• Over the Land the AMI is in wind only mode (only Scatterometer) and the ATSR-2 is in high rate mode. (Due to on board recorder capacity, ATSR-2 in high rate is not compatible with SAR wave imagettes acquisitions.) This strategy preserves the Ocean mission.
• The SAR images are planned as consequence of users' request.

Moreover:
- since July 16th 2003 the ERS-2 Low Rate mission is continued within only the visibility of ESA ground stations over Europe, North Atlantic, the Arctic and western North America. The reason was the failure of both on-board tape recorders.
- During the cycles 64 – 92 (June 2001 since 25th February 2004) the AMI instrument was operated in wind/wave mode also over the land. The reason was because the SAR wave data was used to estimate the satellite mispointing along the full orbit. Since 25th February onwards the nominal mission scenario has been resumed, with the AMI instrument in wind only mode over the land (and consequently ATSR was operated again in High Rate over land). The mispointing performances (in particular the yaw error angle) along the full orbit are computing by analyzing the Scatterometer data.

In order to maximize the data coverage, after the on-board tape recorder failure, an upgrade of the ERS ground segment acquisition scenario has been performed.
In that framework the following has been implemented:

- Since September 7th 2003 the ground station in Maspalomas, Gatineau and Prince Albert are acquiring and processing data for all the ERS-2 satellite passes within the station visibility (apart from passes for which other satellites have an higher priority).

- To further increase the wind coverage of the North Atlantic area, since December 8th, 2003 is operative a new ground Station in West Freugh (UK) and data from this new station are available to the user since mid January 2004. Due to its location, the West Freugh acquisitions have some overlap with those from three other ESA stations, Kiruna, Gatineau or Maspalomas. The station overlap depends on the relative orbit of the satellite. Consequentially, overlapping wind Scatterometer LBR data may be included in two products. Since the two products are generated at different ground stations the overlap may not be completely precise, with a displacement up to 12 Km and slight differences in the wind data itself.

- Since March, 3rd 2004, Matera station is acquiring and processing low rate bit data for all the passes for which is planned a SAR acquisition. This means for the Scatterometer data coverage a limited improvement due to the fact that is acquired only a passage with some planned SAR activity.

- Since February 2005 a new acquisition station in Miami (US) is in operations. This new station allows a full data coverage of the Gulf of Mexico and part of the Pacific Ocean on the west Mexico coast.

- Since 25th, June 2005 a new acquisition stations have been put into operations in Beijing. It covers part of China and Oriental Asia.

- Since 5th July 2005 McMurdo ground station is operational in the South Pole. It covers all the Antarctic region.

- Since 5th December 2005 the Hobart station is operational and it is covering the Australian and New Zealand area. Hobart data has been disseminated into BUFR format since February 13th 2006.

- At the end of August 2006 a new ground station in Singapore has been installed and products are distributed to the users since October 19th 2006.

Figure 8 shows the AMI operational modes for cycle 123. Each segment of the orbit has different color depending on the instrument mode: brown for wind only mode, blue for wind-wave mode and green for image mode. The red and yellow colors correspond to gap modes (no data acquired). For cycle 123 the percentage of the ERS-2 AMI activity is shown in table 4. The value for cycle 123 shows a decrease of SAR activity at descending passes with respect to the cycle 122.

TABLE 4 ERS-2 AMI activity (cycle 123)

Ami Mode	Ascending passes	Descending passes
Wind and Wind-Wave	**94.48 %**	**82.45%**
Image	**0.89 %**	**11.33 %**
Gap and others	**4.6 %**	**6.20 %**

Table 5 reports the major data lost (day or more) due to the test periods, AMI and satellite anomalies or ground segment anomalies occurred after 6th August, 1996 (before that day for many times data were not acquired due to the DC converter failure).

TABLE 5 ERS-2 Scatterometer mission major data lost (day or more) after 6th, August 1996

Start date	Stop Date	Reason
September 23rd, 1996	September 26th, 1996	ERS 2 switched off due to a test period
February 14th, 1997	February 15th, 1997	ERS 2 switched off due to a depointing anomaly
June 3rd, 1998	June 6th, 1998	ERS 2 switched off due to a depointing anomaly
November 17th, 1998	November 18th, 1998	ERS 2 switched off to face out Leonide meteor storm
September 22nd 1999	September 23rd 1999	ERS 2 switched off due to Year 2000 certification test
November 17th, 1999	November 18th, 1999	ERS 2 switched off to face out Leonide meteor storm
December 31st,1999	January 2nd, 2000	ERS 2 switched off Y2K transition operation
February 7th,2000	February 9th, 2000	ERS 2 switched off due to new AOCS s/w up link
June 30th, 2000	July 5th, 2000	ERS 2 Payload switched off after RA anomaly
July 10th, 2000	July 11th, 2000	ERS 2 Payload reconfiguration
October 7th, 2000	October 10th 2000	ERS 2 Payload switched off after AOCS anomaly
January 17th, 2001	February 5th, 2001	ERS 2 Payload switched off due to AOCS anomaly

4.2 PCS Geophysical Monitoring

The routine analysis is summarized in the plots of figure 9; from top to bottom:

• the monitoring of the valid sigma-nought triplets per day.

• the evolution of the wind direction quality. The ERS wind direction (for all nodes and only for those nodes where the ambiguity removal has worked properly) is compared with the ECMWF forecast. The plot shows the percentage of nodes for which the difference falls in the range -90.0, +90.0 degrees.

• the monitoring of the percentage of nodes whose ambiguity removal works successfully.

• the comparison of the wind speed deviation: (bias and standard deviation) with the ECMWF forecast.

The results since August 6th, 1996 until the beginning of the operation with the Zero Gyro Mode (ZGM) in January 2001 can be summarized as:

• High quality wind products has been distributed since Mid March 1996 (end of calibration and validation phase)

• The number of valid sigma-nought distributed per day was almost stable with a small increase after June 29th, 1999 due to the dissemination in fast delivery of the data acquired in the Prince Albert station (Canada).

• The wind direction is very accurate for roughly 93% of the nodes, the ambiguity removal processing successfully worked for more than 90.0% of the nodes.

• The UWI wind speed shows an absolute bias of roughly 0.5 m/s and a standard deviation that ranges from 2.5 m/s to 3.5 m/s with respect to the ECMWF forecast.

• The wind speed bias and its standard deviation have a seasonal pattern due to the different winds distribution between the winter and summer season.

• Two important changes affect the speed bias plot.

• the first is on June 3rd , 1996 due to the switch from ERS-1 to ERS-2 data assimilation in the meteorological model.

• the second which occurred at the beginning of September 1997, is due to the new monitoring and assimilation scheme in ECMWF algorithms (4D-Var).

• Since 19th April 1999 two set of meteo-table (meteorological forecast centred at 00:00 and 12:00 of each day) are used in the ground processing. This allowed the processing of wind data with 18 and 24 hours meteorological forecast instead of the 18, 24, 30 36 hours forecast. The comparison between data processed with the 18-24 hours forecast instead of 30-36 hours forecast shown an increase in the number of ambiguity removed nodes with a neutral impact in the daily statistics.

• The mono-gyro AOCS configuration (see report for cycle 50) that was operative from 7th February 2000 to 17th January 2001 did not affect the wind data performance.

During the Zero Gyro Mode (ZGM) phase the dissemination of the fast delivery Scatterometer data to the users has been interrupted on 17th January 2001 due to degraded quality in sigma noughts and winds. The satellite attitude in ZGM is slightly degraded and the "old" ground processor was not able to produce calibrated data anymore. For that reason a re-design of the entire ground processing has been carried out and since August 21st 2003 the new processor named ERS Scatterometer Attitude Corrected Algorithm (ESACA) is operative in all the ESA ground station and data was redistributed to the user.

Although for a long period data was not distributed, the PCS has monitored the data quality (as shown in Figure 9) and the results during that period can be summarized as:

At the beginning of the ZGM (January 2001 - end July 2001) the number of valid nodes has clear drop from 190000 per day to 9000 per day. This because the satellite attitude was strong degraded and the received signal had a very high Kp figure (in particular for the far range nodes). For the valid nodes, due to no calibrated sigma nought, the quality of the wind was very poor, the distance from the cone was high and the wind speed bias was above 1.5 m/s.

At the end of July 2001 the ZGM has been tuned and the satellite attitude had an improvement. This explains the increase of the number of valid nodes (returned around the nominal level) and the improvements in the wind speed bias (around 0.5 m/s).

On 4th February 2003, a beta version of the new ESACA processor has been put in operation in Kiruna for validation and the monitoring of the data quality has been done only for the new ESACA data. The number of valid nodes slight decreased because Kiruna station process only 9 of 14 orbits per day. The wind speed direction deviation had a clear improvement because ESACA implements a new ambiguity removal algorithm (MSC) and the ambiguity removal rate is now stable at 100% (the MSC is able to remove ambiguity for all the nodes). The wind speed bias had a clear drop from 0.5 to -0.5 m/s. That value is closer to the nominal one (around -0.2 m/s). As reported in the previous cyclic reports the beta version of ESACA had some calibration problem for the near range nodes and this explains why the data quality does not match exactly the one obtained in the nominal YSM. That problem has been overcome with the final release of the ESACA processor put into operation on August 21st 2003. On June 22nd the failure of the on-board tape recorder discontinued the ERS global mission (see section 4.1) and this explains the low number of valid nodes available after that day.

The performances of ESACA winds delivered between August 2003 and September 2004 are affected by land contamination. Around costal zones many Sea nodes have a strong contribution of Land backscattering and the retrieved wind is not correct. An optimization of

the Land/Sea flag in the ground processing has been carried out during the cycle 98. In the statistics computed by PCS on the fast delivered winds the Land contamination has been removed by using a refined Land/Sea mask. Also the ice contamination has been removed with a simple geographical filter. With these new setting the PCS statistics are very similar to the ones reported by ECMWF.

For cycle 123 the wind performances stayed stable. The wind speed bias (UWI vs 18 or 24 hour forecast) was roughly 0.6 m/s and the speed bias standard deviation was around 1.9 m/s. Peaks of 1.3 m/s in wind speed bias on 21st and 22nd February 2007 are due to a reduced number of nodes used in the statistics. .

The wind direction deviation for cycle 123 was good with more than 98% of the nodes wind direction in agreement with the ECMWF forecast.

Reduced number of nodes on 7th and 13rd February are due to instrument anomalies and problems in dissemination chain. Peak on 27th and 28th January is due to missing Gatineau station data.
FIGURE 9 ERS-2 Scatterometer: wind products performance since the beginning of the mission.
FIGURE 10 ERS-2 Scatterometer: wind products performance for cycle 123.

4.3 ECMWF Geophysical Monitoring

The quality of the UWI product was monitored at ECMWF for Cycle 123. Results were compared to those obtained from the previous Cycle, as well for data received during the nominal period in 2000 (up to Cycle 59). No corrections for duplicate observations were applied.

During Cycle 123 data was received between 21:04 UTC 22 January 2007 and 20:58 UTC 26 February 2007. Received data was grouped into 6-hourly batches (centred around 00, 06, 12 and 18 UTC). No data was received for such batches between 18 UTC 23 January and 18 UTC 24 January 2007 (BUFR data was disseminated with delay to meteorological institutes due to problems in dissemination system), 06 UTC 25 January 2007 and 00 UTC 7 February 2007.

Data is being recorded whenever within the visibility range of a ground station. Data coverage for Cycle 123 was over the North-Atlantic, the Mediterranean, the Caribbean, the Gulf of Mexico, a small part of the Pacific west from the US, Canada and Central America, the Chinese and Japanese Sea, a small part of the Indian Ocean South-East of Thailand and Indonesia, and the Southern Ocean around Australia and New Zealand (see Figure 12).

The asymmetry between the fore and aft incidence angles showed a few isolated peaks. The data was flagged accordingly by the combined yaw-k_p flag. The Sun is still near a period of minimal activity. The Earth was under influence of a solar wind stream around 14 February 2007 (source: www.spaceweather.com). There was no sign that this event had affected ERS-2 attitude control.

Compared to Cycle 122, the UWI wind speed relative to ECMWF first-guess (FG) fields showed a somewhat higher standard deviation (1.60 m/s, was 1.55 m/s). Bias levels were slightly less negative (-0.86 m/s, was -0.77 m/s).

The ECMWF assimilation/forecast system was not changed during Cycle 123.

The Cycle-averaged evolution of performance relative to ECMWF first-guess (FG) winds is displayed in Figure 11. Figure 12 shows global maps of the over Cycle 123 averaged UWI data coverage and wind climate, Figure 13 for performance relative to FG winds.
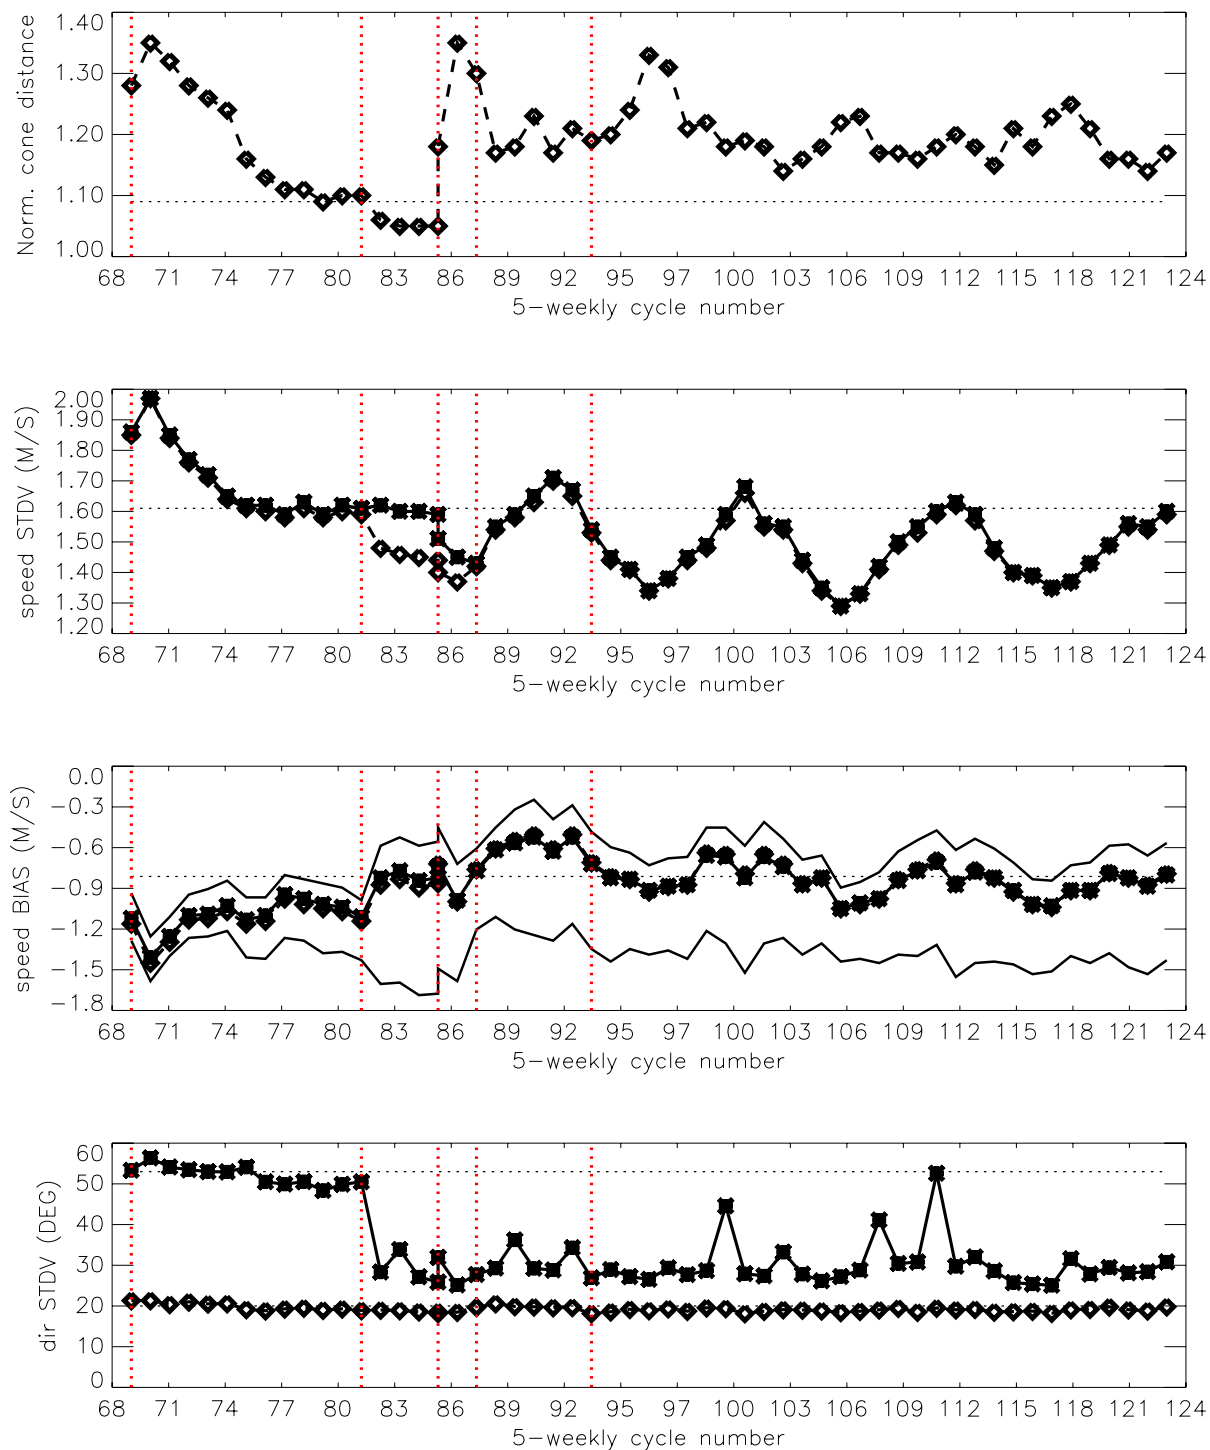

FIGURE 11 Evolution of the performance of the ERS-2 Scatterometer averaged over 5-weekly cycles from 12 December 2001 (cycle 69) to 26 February 2007 (end cycle 123) for the UWI product (solid, star) and de-aliased winds based on CMOD4(dashed, diamond). Results are based on data that passed the UWI QC flags. For cycle 85 two values are plotted; the first value for the global set, the second one for the regional set. Dotted lines represent values for cycle 59 (5 December 2000 to 17 January 2001),i.e. the last stable cycle of the nominal period. From top to bottom panel are shown the normalized distance to the one (CMOD4 only) the standard deviation of the wind speed compared to FG winds, the corresponding bias (for UWI winds the extreme inter-node averages are shown as well),and the standard deviation of wind direction compared to FG.

NOBS (ERS-2 UWI), per 12H, per 125km box
average from 2007012300 to 2007022618 GLOB:2.45
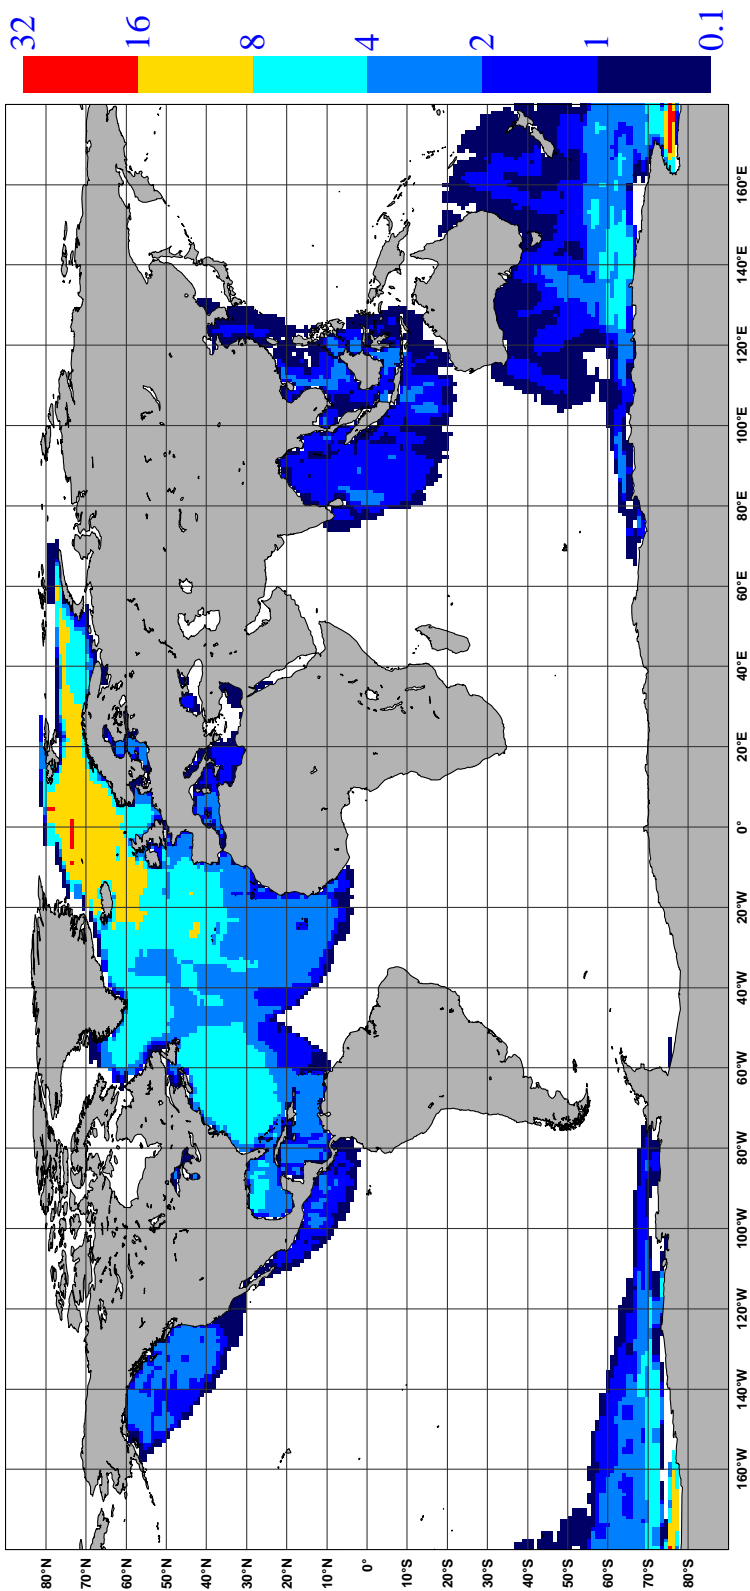

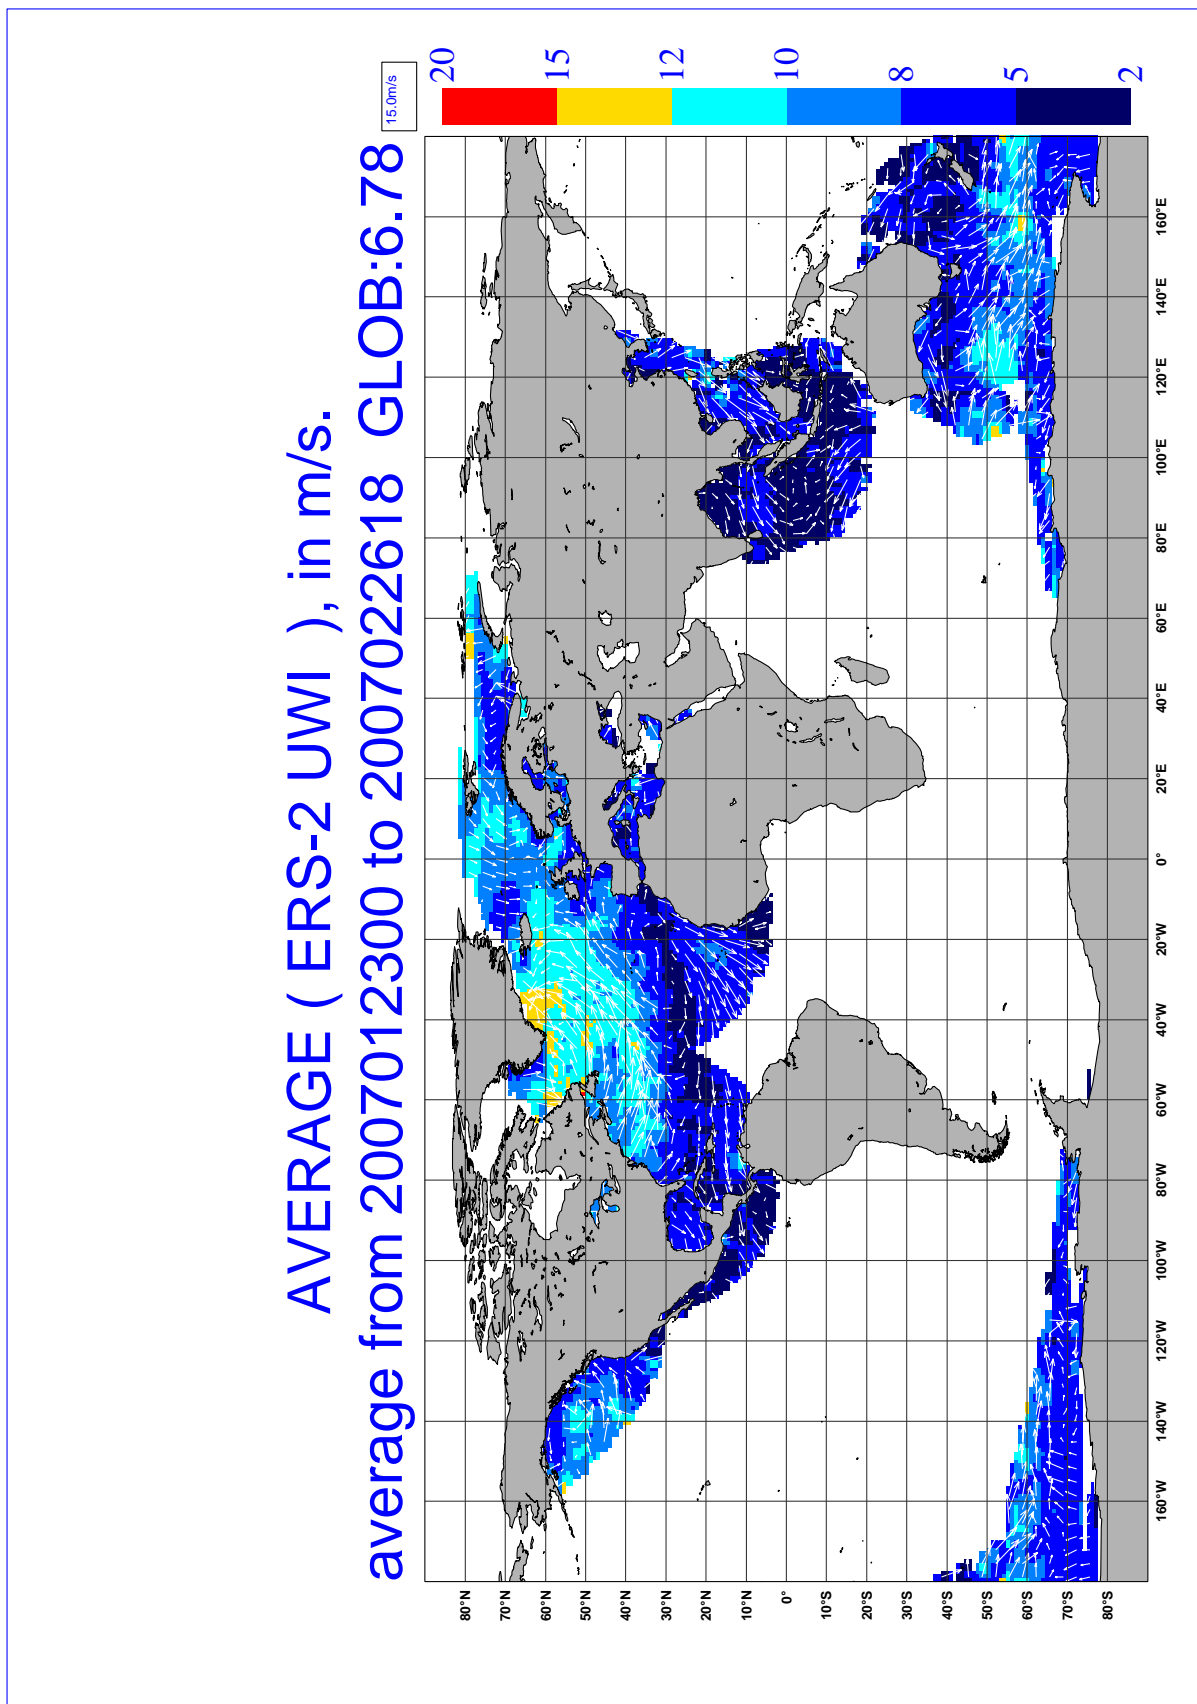

FIGURE 12 Average number of observations per 12H and per 125km grid box (top panel) and wind-climate (lower panel) for UWI winds that passed the UWI flags QC and a check on the collocated ECMWF land and sea-ice mask.

BIAS (ERS-2 UWI vs FIRST-GUESS), in m/s. average from 200701012300 to 200702262618 GLOB:-0.8
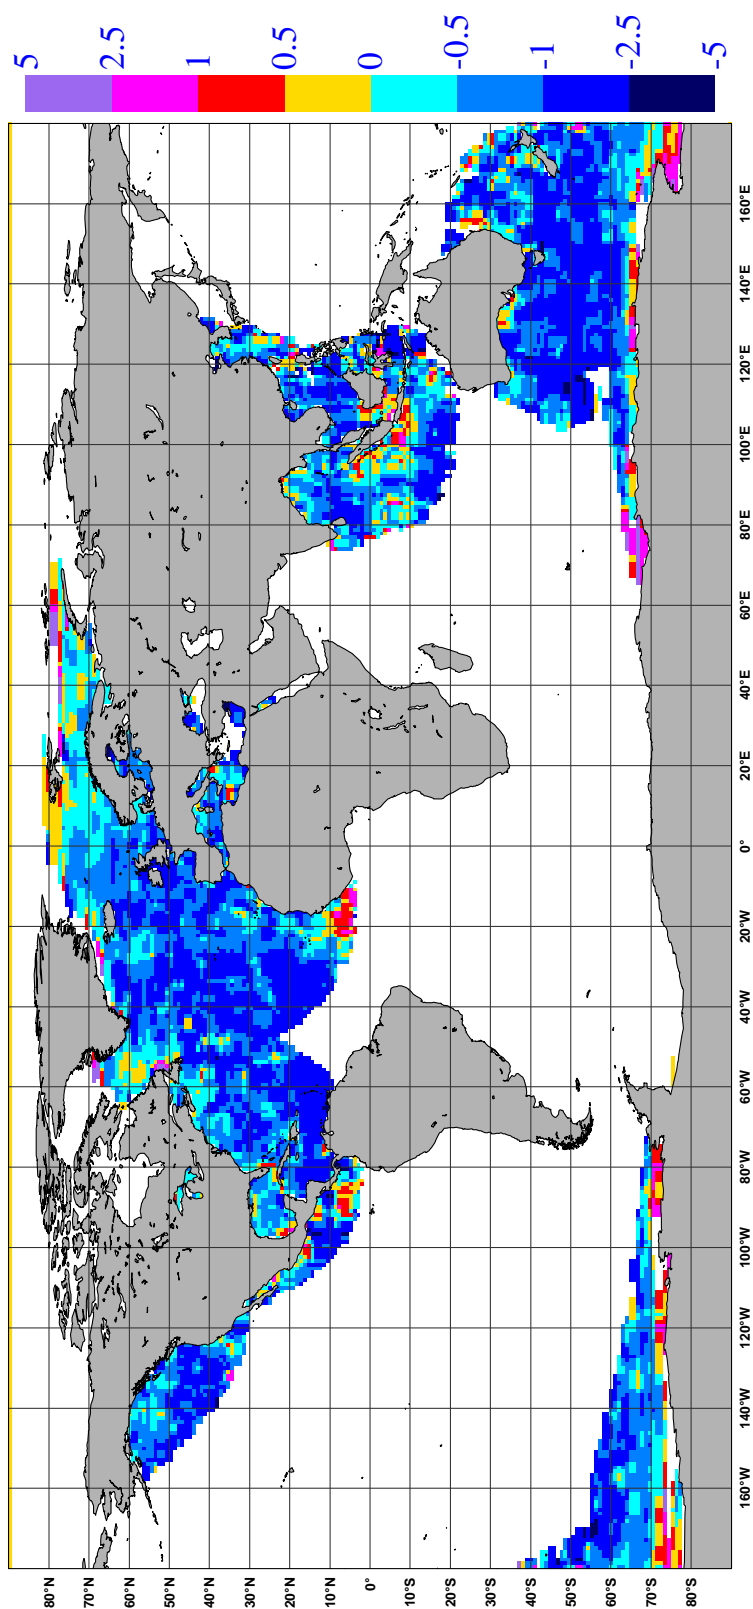

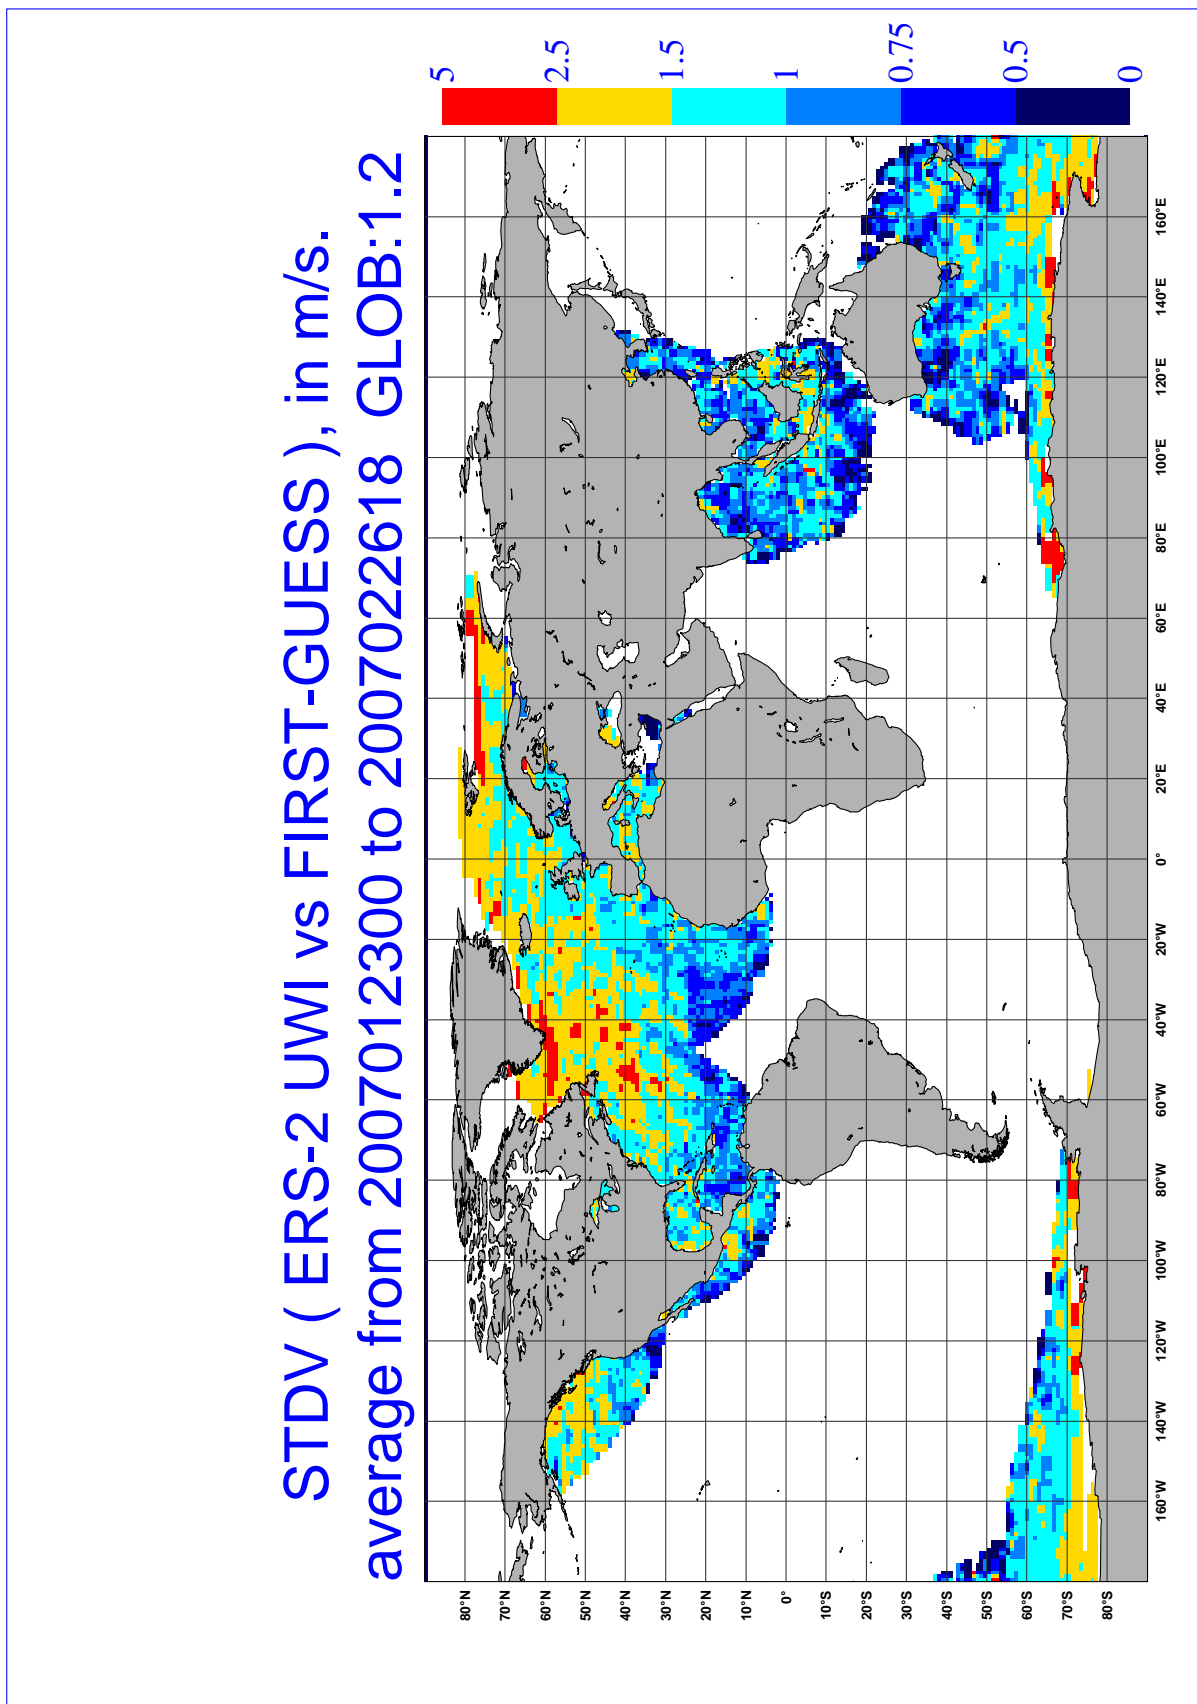

FIGURE 13 The same as Figure 12, but now for the relative bias (top panel) and standard deviation (lower panel) with ECMWF first-guess winds.

4.3.1 Distance to cone history

The distance to the cone history is shown in Figure 14. Curves are based on data that passed all QC, including the test on the K_p-yaw flag, and subject to the land and sea-ice check at ECMWF (see cyclic report 88 for details).

Like for cycle 122, time series are (due to lack of statistics) very noisy, especially for the near-range nodes. Most spikes were found to be the result of low data volumes (such as for 24th January for delay in BURF dissemination, 7th February due to problem in dissemination chain, 13rd February due to missing in many ground station data).

Compared to cycle 122, the average level was slightly lower (1.17), which is about 7% higher than for nominal data (see top panel Figure 11).

The fraction of data that did not pass QC is displayed in Figure 14 as well (dash curves). Peaks often coincide with peaks in yaw anomaly.
FIGURE 14 Mean normalized distance to the cone computed every 6 hours for nodes 1-2, 3-4, 5-7, 8-10, 11-14 and 15-19 (solid curve close to 1 when no instrumental problems are present). The dotted curve shows the number of incoming triplets in logarithmic scale (1 corresponds to 60,000 triplets) and the dashed one indicates the fraction of complete (based on the land and sea-ice mask at ECMWF) sea-located triplets rejected by ESA flags, or by the wind inversion algorithm (0: all data kept, 1: no data kept).

4.3.2 UWI minus First-Guess history

In Figure 15, the UWI minus ECMWF first-guess wind-speed history is plotted. The history plot shows a few peaks, which are usually the result of low data volume. There are signs of temporary degradation after the on-board anomalies on 6 February 2007 and 21 February 2007 (this mainly concerns data for nodes 11-14). Similar results apply for the history of de-aliased CMOD4 winds versus FG (Figure 16).

Figure 19 displays the locations for which UWI winds were more than 8 m/s weaker (top panel) and more than 8 m/s stronger (lower panel) than FG winds. Like for cycle 122, such collocations are isolated, and often indicate meteorologically active regions, for which UWI data and ECMWF model field show reasonably small differences in phase and/or intensity. Deviations near the poles are the result of imperfect sea-ice flagging.

Two cases where UWI and ECMWF wind speed differ significantly are presented in Figure 20.
Top panel shows a complex situation of two merging low pressure systems south of Greenland for 6 February 2007. For the right-hand system the scatterometer winds show a less elongated and slightly shifted vortex. Although the UWI winds look sensible, they do suffer from incorrect de-aliasing near the centre.
The lower panel shows a case in the North Atlantic for 10 February 2007.
In general ECMWF and UWI compare well. However, near the centre of the low, the under-estimation of UWI winds is mainly due to the saturation of the CMOD4 model function for strong winds (better for CMOD5, not shown).

Average bias levels and standard deviations of UWI winds relative to FG winds are displayed in Table 6. From this it follows that the bias of both the UWI and CMOD4 product has become somewhat more negative (from -0.86 m/s to -0.78 m/s), being more or less on the level of nominal data in 2000.

Table 6 Wind speed and direction biases

	Cycle 122		Cycle 123	
	UWI	CMOD4	UWI	CMOD4
Speed STDV	1.55	1.54	1.60	1.59
Node 1-2	1.65	1.61	1.63	1.60
Node 3-4	1.54	1.52	1.55	1.53
Node 5-7	1.49	1.48	1.53	1.52

Node 8-10	1.48	1.47	1.56	1.56
Node 11-14	1.50	1.50	1.58	1.59
Node 15-19	1.52	1.53	1.57	1.58
Speed BIAS	-0.86	-0.85	-0.78	-0.77
Node 1-2	-1.49	-1.45	-1.39	-1.36
Node 3-4	-1.18	-1.12	-1.12	-1.07
Node 5-7	-0.90	-0.87	-0.84	-0.81
Node 8-10	-0.70	-0.70	-0.62	-0.61
Node 11-14	-0.65	-0.66	-0.55	-0.56
Node 15-19	-0.64	-0.66	-0.55	-0.57
Direction STDV	28.4	18.8	30.8	19.8
Direction BIAS	-2.5	-2.3	-1.7	-1.5

On a longer time scale seasonal bias trends are observed (see Figure 11). As was highlighted in the previous cyclic reports, it is believed that this yearly trend is partly induced by changing local geophysical conditions. Strong indication for this is a similar trend observed for QuikSCAT data when restricted to an area well-covered by ERS-2 (20N-90N, 80W-20E).

Figure 25 shows time series for that area for both ERS-2 (top panel) and QuikSCAT (lower panel) for the period between 1 January 2004 and 26 February 2007 (end of cycle 123). Results are displayed for at ECMWF actively assimilated data, i.e., CMOD5 winds for ERS-2 and 4%-reduced QuikSCAT winds on a 50km resolution.

The standard deviation of UWI wind speed versus ECMWF FG was, compared to cycle 122, slightly enhanced (1.56 m/s, was 1.60 m/s).

For cycle 123 the (UWI - FG) direction standard deviations were mostly ranging between 20 and 40 degrees (Figure 17) representing nominal variations. Averaged over the entire cyclic period, STDV for UWI wind direction has grown slightly (30.8 degrees, was 28.4 degrees). For at ECMWF de-aliased winds a similar trend was observed (STDV 19.8 degrees, was 18.8 degrees).

4.3.3 Scatter plots

Scatter plots of FG winds versus ERS-2 winds are displayed in Figures 21 to 24. Values of standard deviations and biases are slightly different from those displayed in Table 6. Reason for this is that, for plotting purposes, the in 0.5 m/s resolution ERS-2 winds have been slightly perturbed (increases scatter with 0.02 m/s), and that zero wind-speed ERS-2 winds have been excluded (decreases scatter with about 0.05 m/s).

The scatter plot of UWI wind speed versus FG (Figure 21) is very similar to that for (at ECMWF inverted) de-aliased CMOD4 winds (Figure 23). It confirms that the ESACA inversion scheme is working properly.

Winds derived on the basis of CMOD5 are displayed in Figure 24. The relative standard deviation is lower than for CMOD4 winds (1.57 m/s versus 1.62 m/s).
Compared to ECMWF FG, CMOD5 winds are 0.23 m/s slower and there is an enhanced tendency for under-estimation at strong winds.

FIGURE 25 Bias relative to FG winds for actively assimilated ERS-2 winds (based on CMOD5) for nodes 1-19 (top panel) respectively of 50-km QuikSCAT (based on the QSCAT-1 model function and reduced by 4%) for nodes 5-34 (lower panels) averaged over the area (20N-90N, 80W-20E), and displayed for the period 01 January 2004 – 26 February 2007. Fat curves represent centered 15-day running means, thin curves values for 6-hourly period. Vertical dashed blue lines mark ECMWF model changes

5   Yaw error angle estimation

The yaw error angle estimation is computed on-ground by the ESACA processors. The full set of results of the yaw processing is stored in an internal ESA product named HEY (Helpful ESA Yaw) disseminated from the ground station to ESRIN. The estimation of the yaw error angle is based on the Doppler shift measured on the received echo. That estimation can be done with a good accuracy only for small yaw error angle (in the range between +/-4 deg.). Above that range, due to high Doppler frequency shift the signal spectrum is outside the receiver bandwidth and the yaw estimation is strong degraded. Details regarding the yaw processing can be found on the following document (chapter 9): http://earth.esa.int/pcs/ers/scatt/articles/soamain-030521.pdf .

The yaw error angle estimation aims to compute the correct acquisition geometry for the three Scatterometer antenna throughout the entire orbit. The Yaw error angle information is used in the radar equation to derive the calibrated backscattering (sigma nought) from the Earth surface and to select the echo samples associated to one node. In ESACA the definition of the node position is as the one adopted in the old processor (for details see:.http://earth.esa.int/pcs/ers/scatt/articles/scatt_work98_processing.pdf). In such way the distance between the nodes (both along and across track) is kept constant (25 Km) and what is changing in function of the yaw error angle is the number of echo samples that contributes to the node calculation and the incidence angle of the measurement. This because the three Scatterometer antennae could see the node with a different geometry due to an arbitrary variation of the yaw angle along track. The number of samples that actually contributes to a node and the yaw flag can be retrieved from the UWI Data Set Record (DSR) product. For that reason the definition of few fields in the UWI product has been updated. For details see the Scatterometer cyclic report - cycle 90 -. The Figure 26 (since beginning of HEY dissemination) and Figure 27 (cycle) show for each orbit the average Doppler frequency shift (first 3 plots Fore Mid and Aft antenna), the minimum, maximum and mean yaw (fourth plot), the yaw standard deviation (fifth plot) and the percentage of source packets acquired with a yaw error angle outside the range +/- 2 degrees (sixth plot). On average the yaw evolution is within the specification for the ESACA processor to assure calibrated data. The evolving yaw bias occurred in June 2004 has been reported to the flight segment and corrective actions have been put in place to compensate for.

The result of the monitoring for cycle 123 is an average (per orbit) yaw error angle within the expected nominal range (+/- 2 degrees) for most of the orbit. The orbits affected by the manoeuvre performed on 1, 13 and 14 February are identified by the peaks in the plot of the yaw angle standard deviation evolution. On February 7th and 13th only few orbits are available to compute the statistics. This was due to instrument anomaly and problem on dissemination chain.
